Election Vote Counting

Description

Counting election votes and determining election results by different methods, including the single transferable vote (ranked choice), approval, score, plurality, condorcet and two-round runoff methods. Details about the methods and package functions can be found in Raftery et al. (2021).

Details

The main function of the package is called count.votes. If no specific method is passed, it decides on the basis of the available data which method is the most appropriate. Specific methods can also be invoked explicitly. The following voting methods are available:

- stv: Single transferable vote (STV) where voters rank candidates in order. It is also known as ranked choice voting or instant runoff.
- score: Range voting where each voter gives each candidate a score within a specific range.
- approval: Voters give each candidate one (approve) or zero (not approve).
- plurality: Each voter chooses one candidate.
- condorcet: Voters rank candidates in order. The winner is determined in pairwise comparisons.
- tworound.runoff: Two-round majority system with ranked ballots. If no candidate gets the majority, there is a run-off between the top two candidates.

Output of these functions can be viewed using summary methods, or in a browser using view methods. The summary methods return a data frame which can be stored in a file, see Example below. Outputs of the stv method can be plotted in a graph. The joint and marginal distributions of ranked votes (for stv, condorcet and tworound.runoff) can be visualized in an image plot.

Functions invalid.votes, valid.votes and corrected.votes can be used to check the validity of ballots for the various methods, including corrections made within the methods. Function correct.ranking can be used to make ballot corrections to ranked data, including ballots with equal preferences.

Example datasets are included. The ims_election dataset contains anonymized ballots from a past Council election of the Institute of Mathematical Statistics (IMS) which uses the STV method. Modifications of this dataset are available (ims_approval, ims_score, ims_plurality) as examples of data required by the various methods. The food_election dataset taken from Wikipedia can be used to test the STV method. Similarly, methods for ranked voting can be applied to the dublin_west dataset which contains election ballots from the 2002 election to the Dublin West constituency in Ireland.

Examples

```
data(ims_election)
res <- count.votes(ims_election, method = "stv", nseats = 5)
summary(res)

# View invalid votes
invalid.votes(res)

## Not run:
# View results in a browser
view(res)

# Write election results into a csv file
s <- summary(res)
write.csv(s, "IMSstvresults.csv")
## End(Not run)</pre>
```

approval

Approval and Plurality Vote Count

Description

Count votes using the approval and plurality methods. Each voter can select candidates using 1 for a selection and 0 otherwise. In the approval method, any number of candidates can be selected by a voter, while in the plurality method only one candidate can be chosen by a voter. Thus, plurality voting is a special case of approval voting. The winner(s) in either method is/are the most-approved candidate(s).

Usage

```
approval(votes, nseats = 1, fsep = "\t", quiet = FALSE, ...)
## S3 method for class 'vote.approval'
summary(object, ...)
## S3 method for class 'vote.approval'
view(object, ...)
plurality(votes, nseats = 1, fsep = "\t", quiet = FALSE, ...)
## S3 method for class 'vote.plurality'
summary(object, ...)
```

4 approval

```
## S3 method for class 'vote.plurality'
view(object, ...)
```

Arguments

votes Matrix or data frame of zeros and ones containing the votes. Rows correspond

to the votes, columns correspond to the candidates. If it is a character string it is interpreted as a file name from which the votes are to be read. Missing values

(NA) are interpreted as zeros.

nseats Number of candidates to be elected.

fsep If votes is a file name, this argument gives the column separator in the file.

quiet If TRUE no output is printed.

... Not used.

object Object of class vote.approval or vote.plurality.

Value

Functions approval and plurality return an object of class vote. approval and vote. plurality, respectively, both of which are lists with the following objects:

elected Vector of names of the elected candidates in the order in which they were

elected.

totals Vector of total votes in the same order as candidates (columns) in the input data.

data Input data with invalid votes removed.

invalid.votes Matrix of invalid votes that were removed from the original dataset.

condorcet

Condorcet Vote Count

Description

Count votes using the Condorcet voting method.

Usage

```
condorcet(votes, runoff = FALSE, fsep = '\t', quiet = FALSE, ...)
## S3 method for class 'vote.condorcet'
summary(object, ...)
## S3 method for class 'vote.condorcet'
view(object, ...)
## S3 method for class 'vote.condorcet'
image(x, ...)
```

Arguments

votes	Matrix or data frame containing the votes. Rows correspond to the votes, columns correspond to the candidates. If it is a character string it is interpreted as a file name from which the votes are to be read. See below for more details.
runoff	Logical. If TRUE and no condorcet winner exists, the election goes into a run-off, see below for details.
fsep	If votes is a file name, this argument gives the column separator in the file.
quiet	If TRUE no output is printed.
object,x	Object of class vote.condorcet.
•••	Additional arguments passed to the underlying functions. For the image function, see arguments for image.vote.stv, especially xpref, ypref, all.pref and proportion.

Details

The Condorcet method elects the candidate that wins a majority of the ranked vote in every head-to-head election against each of the other candidates. I.e., the Condorcet winner is a candidate that beats all other candidates in pairwise comparisons. Analogously, a Condorcet loser is a candidate that loses against all other candidates. Neither Condorcet winner nor loser might exist.

If the runoff argument is set to TRUE and no Condorcet winner exists, two or more candidates with the most pairwise wins are selected and the method is applied to such subset. If more than two

6 condorcet

candidates are in such run-off, the selection is performed repeatedly, until either a winner is selected or no more selection is possible.

The input data votes is structured the same way as for the stv method: Row i contains the preferences of voter i numbered $1, 2, \ldots, r, 0, 0, 0, 0$, in some order, while equal preferences are allowed. The columns correspond to the candidates. The dimnames of the columns are the names of the candidates; if these are not supplied then the candidates are lettered A, B, C, If the dataset contains missing values (NA), they are replaced by zeros.

Note that if equal preferences are used, they are automatically converted into a format where for each preference i that does not have any duplicate, there must be exactly i-1 preferences j with 0 < j < i. It is the same ranking as one would obtain with rank(x, ties.method = "min"). If a conversion of a vote occurs, a warning is issued. That is done internally by calling the correct.ranking function.

The image function visualizes the joint distribution of two preferences (if all.pref=FALSE) given by xpref and ypref, as well as the marginal distribution of all preferences (if all.pref=TRUE). The joint distribution can be shown as proportions (if proportion=TRUE) or raw vote counts (if proportion=FALSE).

Value

Function condorcet returns an object of class vote.condorcet which is a list with the following objects:

elected The Condorcet winner if exists, otherwise NULL.

loser The Condorcet loser if exists, otherwise NULL.

totals $nc \times nc$ matrix where nc is the number of candidates. Element ij = 1 if i won

against j, otherwise 0.

runoff.winner The run-off winner if exists and if the runoff argument was set to TRUE, other-

wise NULL.

runoff.participants

List of run-off participants if the runoff argument was set to TRUE, otherwise

NULL.

data Input data (possibly corrected) with invalid votes removed.

invalid.votes Matrix of invalid votes that were removed from the original dataset.

count.votes 7

Examples

count.votes

Count Votes

Description

Count votes using one of five methods. View valid, invalid and corrected ballots.

Usage

Arguments

votes	Matrix or data frame containing the votes. Rows correspond to the votes, columns correspond to the candidates. If it is a character string it is interpreted as a file name from which the votes are to be read.
method	Voting method to use. If "auto", the input data is passed through a checker for each of the methods and the one with the largest number of valid votes is used. In case of the same number of valid votes, it goes by their ordering in the function definition.
fsep	If votes is a file name, this argument gives the column separator in the file.
•••	Additional arguments passed to the underlying functions, e.g. \mbox{nseats} , $\mbox{max.score}$ etc.
object	Object returned by one of the functions plurality, approval, stv, score, condorcet, tworound.runoff.

8 dublin_west

Value

Depending which method is used, count.votes returns an object of class vote.plurality, vote.approval, vote.stv, vote.score, vote.condorcet, or vote.tworound.runoff.

Functions valid.votes and invalid.votes return a subset of the input data with valid records and invalid records, respectively.

Function corrected.votes can be used when votes are automatically corrected (as in stv and condorcet). It returns a list with the uncorrected votes (item original), the corrected votes (item new), and its indices within the original votes dataset (item index).

```

dublin_west

Election Dataset to Dublin West Constituency

Description

Dataset containing ranked votes for the Dublin West constituency in 2002, Ireland. Results of that STV elections can be viewed at https://en.wikipedia.org/wiki/Dublin_West#2002_general_election. They can be reproduced via the stv function, see Example below.

Usage

```
data("dublin_west")
```

Format

A data frame with 29988 observations and 9 candidates. Each record corresponds to one ballot with candidates being ranked between 1 and 9 with zeros allowed.

food_election 9

References

https://en.wikipedia.org/wiki/Dublin_West#2002_general_election

Examples

```
data(dublin_west)
head(dublin_west)

## Not run:
# produce similar results as in the Wikipedia link above
dwstv <- stv(dublin_west, nseats = 3, eps = 1, constant.quota = TRUE)

# plot results
plot(dwstv)
image(dwstv)
image(dwstv, all.pref = TRUE)
## End(Not run)</pre>
```

food_election

Example Dataset

Description

Dataset on food election which serves as a simple example for the STV method taken from Wikipedia.

Usage

```
data("food_election")
```

Format

A data frame with 20 observations and 5 candidates (Oranges, Pears, Chocolate, Strawberries, Sweets). Each record corresponds to one ballot with ranking for each of the candidates.

Source

```
https://en.wikipedia.org/wiki/Single_transferable_vote#Example
```

Examples

```
data(food_election)
head(food_election)
```

ims_election

 $ims_election$

Datasets on IMS Election

Description

Datasets containing anonymized votes for a past Council election of the Institute of Mathematical Statistics (IMS). The dataset ims_election (named also ims_stv) is the original dataset used with single transferable vote, where candidate names have been changed. Each of the other datasets is a modified version of the original data to be used as an example for each of the other voting methods.

Usage

```
data("ims_election")
data("ims_stv")

data("ims_approval")
data("ims_score")
data("ims_plurality")
```

Format

A data frame with 620 observations and 10 candidates (names were made up). Each record corresponds to one ballot. Values depend on the voting method. The IMS Council voting is done using the STV method, and thus the ims_election dataset contains ballots with candidates being ranked between 1 and 10 with zeros allowed.

Source

The original dataset (which was randomized and anonymized, with write-in votes removed) was obtained from the Institute of Mathematical Statistics.

References

Examples

```
data(ims_election)
head(ims_election)
```

score 11

|--|

Description

Count votes using the score (or range) method. Voters give each candidate a score, the scores are added and the candidate(s) with the highest (or lowest) totals is/are elected.

Usage

```
score(votes, nseats = 1, max.score = NULL, larger.wins = TRUE,
  fsep = "\t", quiet = FALSE, ...)

## S3 method for class 'vote.score'
summary(object, ...)

## S3 method for class 'vote.score'
view(object, ...)
```

Arguments

votes	Matrix or data frame containing the votes which should be numbers between 0 and max.score. Rows correspond to the votes, columns correspond to the candidates. If it is a character string it is interpreted as a file name from which the votes are to be read. Missing values (NA) are interpreted as zeros.
nseats	Number of candidates to be elected.
max.score	Maximum score allowed. It is used to remove invalid votes. If not given, the maximum value contained in the data is taken and thus, all non-negative votes are valid.
larger.wins	Logical argument indicating whether the winners are the candidates with the highest scores (default) or the lowest scores.
fsep	If votes is a file name, this argument gives the column separator in the file.
quiet	If TRUE no output is printed.
	Not used.
object	Object of class vote.score.

Value

Function score returns an object of class vote. score which is a list with the following objects:

elected	Vector of names of the elected candidates in the order in which they were elected.
totals	Vector of total votes in the same order as candidates (columns) in the input data.
larger.wins	Input argument of the same name.
data	Input data with invalid votes removed.
invalid.votes	Number of invalid votes that were removed from the original dataset.

stv

Single Transferable Vote

Description

Count votes using the single transferable voting method, also known as ranked choice voting or instant runoff. Raftery et al. (2021) describes the functionality in great detail.

Usage

```
stv(votes, nseats = NULL, eps = 0.001, equal.ranking = FALSE,
  fsep = '\t', ties = c("f", "b"), constant.quota = FALSE,
  quota.hare = FALSE, group.nseats = NULL, group.members = NULL,
  complete.ranking = FALSE, invalid.partial = FALSE,
  impute.missing = FALSE, verbose = FALSE, seed = 1234,
  quiet = FALSE, digits = 3, ...)

## S3 method for class 'vote.stv'
summary(object, ..., complete.ranking = FALSE, digits = 3)

## S3 method for class 'vote.stv'
view(object, ...)

## S3 method for class 'vote.stv'
plot(x, xlab = "Count", ylab = "Preferences", point.size = 2, ...)

## S3 method for class 'vote.stv'
image(x, xpref = 2, ypref = 1, all.pref = FALSE, proportion = TRUE, ...)
```

```
## S3 method for class 'vote.stv'
complete.ranking(object, ...)

correct.ranking(votes, partial = FALSE, quiet = FALSE)

impute.ranking(votes, equal.ranking = FALSE, quiet = TRUE)

remove.candidate(votes, can, quiet = TRUE)

ordered.tiebreak(vmat, seed = NULL)

ordered.preferences(vmat)
```

Arguments

votes Matrix or data frame containing the votes. Rows correspond to the votes, columns

correspond to the candidates. If it is a character string it is interpreted as a file

name from which the votes are to be read. See below for more details.

nseats Number of candidates to be elected. By default it is half the number of candi-

dates standing.

eps Value added to the quota. I.e. the STV default Droop quota is computed as

number_of_first_preferences/(number_of_seats + 1) + eps.

equal.ranking If TRUE equal preferences are allowed, see below.

fsep If votes is a file name, this argument gives the column separator in the file.

ties Method used to break ties. By default the forwards tie-breaking is used ("f").

Value "b" invokes the backwards tie-breaking method, see O'Neill (2004).

constant. quota Logical determining if the quota should be kept constant for all counts.

quota.hare Changes quota calculation method from (default) Droop (FALSE) to Hare (TRUE).

STV Hare quota method is computed as

number_of_first_preferences/number_of_seats + eps. The actual Hare

formula would entail eps = 0.

group.nseats Minimum number of candidates to be elected who are members of a given

group. I.e., number of reserved seats for a subset of candidates defined by the

group.members argument.

group.members Vector of candidate names or indices who are eligible for reserved seats given

by group.nseats. If it is a vector of indices, the order of candidates is assumed

to correspond to the columns of votes.

impute.missing Logical. If TRUE and if the data contains values of -1, those ranks are imputed

while all other ranks that are equal or larger than the imputed value are shifted.

verbose Logical. If TRUE the progress of the count will be printed.

seed Integer. Seed of the random number generator. Only used if there are ties that

cannot be resolved by the tie-breaking method. If set to NULL, the RNG is not

initialized.

quiet If TRUE no output is printed. object, x Object of class vote.stv.

complete.ranking

Logical. If TRUE a complete ranking is generated conditioned on the number of seats nseats.

invalid.partial

Logical. If TRUE, partially invalid votes are corrected by removing ranking start-

ing with the first incorrect rank, see Details below.

digits How many significant digits to be used in the output table.

xlab, ylab Labels of the x- and y-axis.
point.size Size of the points in the plot.

xpref, ypref Preference for the x- and y-axis, respectively, for showing the joined distribution

of the votes. It is not used if all.pref is TRUE.

all.pref Logical. If TRUE the marginal distribution of all preferences is shown in the

image. Otherwise, the joint distribution of xpref and ypref is shown.

proportion If TRUE the preferences are shown as proportions across the x-axis, otherwise

raw vote counts are shown. Only available when all.pref is FALSE.

. . . Additional arguments passed to the underlying functions.

partial Logical. The same meaning as invalid.partial.

can Vector of candiate name(s) or indices to be removed from the set of votes.

vmat Matrix of valid votes.

Details

For a description of the single transferable vote system see https://imstat.org/elections/single-transferable-voting-system/.

The input data votes is structured as follows: Row i contains the preferences of voter i numbered $1, 2, \ldots, r, 0, 0, 0, 0$, in some order. The columns correspond to the candidates. The dimnames of the columns are the names of the candidates; if these are not supplied then the candidates are lettered A, B, C, If the dataset contains missing values (NA), they are replaced by zeros, representing lower preferences that were not expressed.

By default the preferences are not allowed to contain duplicates per vote. However, if the argument equal.ranking is set to TRUE, votes are allowed to have the same ranking for multiple candidates. The desired format is such that for each preference i that does not have any duplicate, there must be exactly i-1 preferences j with 0 < j < i. For example, valid ordered preferences are $1,1,3,4,\ldots$, or $1,2,3,3,3,6,\ldots$, but NOT $1,1,2,3,\ldots$, or NOT $1,2,3,3,3,5,6,\ldots$. If the data contain such invalid votes, they are automatically corrected and a warning is issued by calling the correct.ranking function.

If equal ranking is not allowed (equal.ranking = FALSE), the argument invalid.partial can be used to make ballots containing duplicates or gaps partially valid. If it is TRUE, a ballot is considered valid up to a preference that is in normal case not allowed. For example, ballots 1,2,3,4,4,6 or 1,2,3,5,6,7 would be both converted into 1,2,3,0,0,0, because the ballots contain valid ranking only up to the third preference.

The correct.ranking function does the above corrections for all records, regardless if they contain duplicates or not. Its argument partial determines if ballots are partially set to 0 (TRUE), or if it is complete re-ranking, as allowed when equal.ranking = TRUE. It can either be used by calling it explicitly, otherwise it is called by stv if equal.ranking = TRUE or invalid.partial

= TRUE. The function is also called from within the condorcet function. The remove.candidate function removes the given candidate(s) and adjusts the ranked votes accordingly by calling the correct.ranking function.

The function allows the user to impute missing values. It can be used for example, if a voter has a conflict of interest with one or more candidates and not voting for them would unfairly decrease the chances of those candidates being elected. (Note that missing values are not to be confused with lower preferences that are not expressed.) Preferences to be imputed should be set to -1 and the argument impute.missing to TRUE. Each such preference is imputed using the median rank value over the remaining votes. When computing the median rank across the votes, any value of zero is replaced by the median of the ranks not used in the corresponding vote. For example, for a ballot 1, 2, 3, 0, 0, 0, the three zeros are replaced by the median of 4, 5, 6, i.e. by 5, which is then used to compute the missing median rank. If the final imputed rank is larger than the number of non-zero preferences (e.g. if in a ballot 1, 2, 0, -1, 0 the imputed value for the fourth candidate would be larger than 3), the preference is set to zero and a warning is issued. The described functionality is implemented in the impute.ranking function, which is called automatically from stv if impute.missing = TRUE. It can be used explicitly as well.

By default, ties in the STV algorithm are resolved using the forwards tie-breaking method, see Newland and Briton (Section 5.2.5). Argument ties can be set to "b" in order to use the backwards tie-breaking method, see O'Neill (2004). In addition, both methods are complemented by the following "ordered" method: Prior to the STV election candidates are ordered by the number of 1st preferences. Equal ranks are resolved by moving to the number of 2nd preferences, then 3rd and so on. Remaining ties are broken by random draws. Such complete ordering is used to break any tie that cannot be resolved by the forwards or backwards method. If there is at least one tie during the processing, the output contains a row indicating in which count a tie-break happened (see the ties element in the Value section for an explanation of the symbols).

The ordered tiebreaking described above can be analysed from outside of the stv function by using the ordered.tiebreak function for viewing the a-priori ordering (the highest number is the best and lowest is the worst). Such ranking is produced by comparing candidates along the columns of the matrix returned by ordered.preferences.

The plot function shows the evolution of the total score for each candidate as well as the quota. The image function visualizes the joint distribution of two preferences (if all.pref=FALSE) as well as the marginal distribution of all preferences (if all.pref=TRUE). The joint distribution can be shown either as proportions (if proportion=TRUE) or raw vote counts (if proportion=FALSE).

Method complete.ranking produces a complete ranking of the candidates, conditioned on the number of seats selected in the nseats argument. It is called from the summary function if the complete.ranking argument is set to TRUE.

Value

Function stv returns an object of class vote. stv which is a list with the following objects:

elected Vector of names of the elected candidates in the order in which they were

elected.

preferences Matrix of preferences. Columns correspond to the candidates and rows to the

counts (i.e. voting rounds).

quotas Vector of quotas, one for each count.

elect.elim Matrix of the same shape as preferences. Value 1 means that the corresponding candidate was elected in that round; value -1 means an elimination.

equal.pref.allowed

Input argument equal.ranking.

ties Character vector indicating if and what tie-break happened in each count. Possi-

ble values: "" (no tie-break), "f" (forward tie-breaking method only), "fo" (forward method and ordered method), "fos" (forward method and ordered method and sampling). If the backwards tie-breaking method is used, these values are

"b", "bo" and "bos".

data Input data (possibly corrected) with invalid votes removed.

invalid.votes Matrix of invalid votes that were removed from the original dataset.

corrected.votes

List containing data about corrected votes if any. It has three or four elements, original (matrix of the raw votes that were corrected), (optionally) imputed (imputed values if any), new (the corrected values), index (index of those votes

within the input votes dataset).

reserved.seats Number of reserved seats (group.nseats), or NULL if none.

group.members Vector of candidates eligible for reserved seats, or NULL if none.

The summary function returns a data frame where columns are counts and transfers, and rows are the quota, the candidates, ties and the elected and eliminated candidates. Various attributes of the data frame contain more information about the results.

The correct.ranking (impute.ranking) function returns a matrix of votes with corrected (imputed) preferences.

remove.candidate returns a matrix of votes with the given candidates removed and preferences corrected.

complete.ranking returns a data frame with a full ordering of the candidates.

ordered.preferences returns a matrix with number of preferences for each candidate and preference. These are the same values as seen by image(..., all.pref = TRUE).

ordered.tiebreak returns the ranking for each candidate based on ordered.preferences(), with the highest number being the best and the lowest number being the worst. Its attribute "sampled" indicates if there was random sampling involved in ranking each candidate.

tworound.runoff

Two-Round Runoff Vote Count

Description

Count votes using the two-round voting method with ranked ballots. If no candidate reaches the majority, the top two candidates go into a run-off.

Usage

```
tworound.runoff(votes, fsep = '\t', seed = NULL, quiet = FALSE, ...)
## S3 method for class 'vote.tworound.runoff'
summary(object, ...)
## S3 method for class 'vote.tworound.runoff'
view(object, ...)
## S3 method for class 'vote.tworound.runoff'
image(x, ...)
```

tworound.runoff

Arguments

votes Matrix or data frame containing the votes. Rows correspond to the votes, columns

correspond to the candidates. If it is a character string it is interpreted as a file

name from which the votes are to be read. See below for more details.

fsep If votes is a file name, this argument gives the column separator in the file.

seed Integer. Seed of the random number generator (RNG). Only used if there are

ties either between candidates to enter the run-off, or between the two run-off

contenders. If set to NULL, the RNG is not initialized.

quiet If TRUE no output is printed.

object, x Object of class vote.tworound.runoff.

.. Additional arguments passed to the underlying functions. For the image func-

tion, see arguments for image.vote.stv, especially xpref, ypref, all.pref

and proportion.

Details

First, the number of first preferences is counted. If there is a candidate with more than 50%, that candidate gets elected. Otherwise, there is a runoff between the top two candidates.

The input data votes is structured the same way as for the stv method: Row i contains the preferences of voter i numbered $1, 2, \ldots, r, 0, 0, 0, 0$, in some order. Equal preferences are not allowed. The columns correspond to the candidates. The dimnames of the columns are the names of the candidates; if these are not supplied then the candidates are lettered A, B, C, If the dataset contains missing values (NA), they are replaced by zeros.

The image function visualizes the joint distribution of two preferences (if all.pref=FALSE) given by xpref and ypref, as well as the marginal distribution of all preferences (if all.pref=TRUE). The joint distribution can be shown as proportions (if proportion=TRUE) or raw vote counts (if proportion=FALSE).

Value

Function tworound.runoff returns an object of class vote.tworound.runoff which is a list with the following objects:

elected The elected candidate.

totals Vector of total votes in the same order as candidates (columns) in the input data.

totals2r Vector of total votes from the run-off (second round).

coin.toss.winner

TRUE if the winner was sampled between candidates with the same score, other-

wise FALSE.

coin.toss.runoff

TRUE if the run-off contenders were sampled from candidates with the same

score. Otherwise it is FALSE.

data Input data (possibly corrected) with invalid votes removed.

invalid.votes Matrix of invalid votes that were removed from the original dataset.

20 tworound.runoff
