1 Introduction

Functional similarity of gene products can be estimated by controlled biological vocabularies, such as Gene Ontology (GO). GO comprises of three orthogonal ontologies, i.e. molecular function (MF), biological process (BP), and cellular component (CC).

Four methods have been presented to determine the semantic similarity of two GO terms based on the annotation statistics of their common ancestor terms (Resnik (Philip, 1999), Jiang (Jiang and Conrath, 1997), Lin (Lin, 1998) and Schlicker (Schlicker et al., 2006)). Wang (Wang et al., 2007) proposed a new method to measure the similarity based on the graph structure of GO. Each of these methods has its own advantages and weaknesses. *GOSemSim* package (Yu et al., 2010) is developed to compute semantic similarity among GO terms, sets of GO terms, gene products, and gene clusters, providing both five methods mentioned above. I have developed another package, *DOSE*, for measuring semantic similarity among DO terms and gene products at disease perspective.

To start with *GOSemSim* package, type following code below:

```
> library(GOSemSim)
> help(GOSemSim)
```

3 Semantic Similarity Measurement Based on GO

Four methods proposed by Resnik (Philip, 1999), Jiang (Jiang and Conrath, 1997), Lin (Lin, 1998) and Schlicker (Schlicker et al., 2006) are information content (IC) based, which depend on the frequencies of two GO terms involved and that of their closest common ancestor term in a specific corpus of GO annotations. The information content of a GO term is computed by the negative log probability of the term occurring in GO corpus, and is defined as $IC(t) = -\log p(t)$. A rarely used term contains a greater amount of information.

At present, *GOSemSim* supports analysis on many species. We used the following Bioconductor packages to calculate the information content.

- org.At.tair.db for *Arabidopsis*
- org.Ag.eg.db for *Anopheles*
- org.Bt.eg.db for *Bovine*
- org.Cf.eg.db for *Canine*
- org.Gg.eg.db for *Chicken*
- org.Pt.eg.db for *Chimp*
- org.Sco.eg.db for *Coelicolor*
- org.EcK12.eg.db for *E coli strain K12*
- org.EcSakai.eg.db for *E coli strain Sakai*
- org.Dm.eg.db for *Fly*
- org.Hs.eg.db for *Human*
- org.Pf.plasmo.db for *Malaria*
- org.Mm.eg.db for *Mouse*
- org.Ss.eg.db for *Pig*
- org.Rn.eg.db for *Rat*
- org.Mmu.eg.db for *Rhesus*
- org.Ce.eg.db for *Worm*
- org.Xl.eg.db for *Xenopus*
- org.Sc.sgd.db for *Yeast*
- org.Dr.eg.db for *Zebrafish*

The information content will update regularly.

As GO allow multiple parents for each concept, two terms can share parents by multiple paths. We take the most informative common ancestor (MICA), where there is more than one shared parents.

- Resnik's method is defined as:

$$sim_{Resnik}(t_1, t_2) = IC(MICA)$$

- Lin's method is defined as:

$$sim_{Lin}(t_1, t_2) = \frac{2IC(MICA)}{IC(t_1)+IC(t_2)}$$

- The Relevance method, which was proposed by Schlicker's method, combine Resnik's and Lin's method, and is defined as:

$$sim_{Rel}(t_1, t_2) = \frac{2IC(MICA)(1-p(MICA))}{IC(t_1)+IC(t_2)}$$

- Jiang and Conrath's method is defined as:

$$sim_{Jiang}(t_1, t_2) = 1 - \min(1, d_{Jiang}(t_1, t_2))$$

where

$$d_{Jiang}(t_1, t_2) = IC(t_1) + IC(t_2) - 2IC(MICA)$$

Graph-based methods using the topology of GO graph structure to compute semantic similarity. Formally, a GO term A can be represented as $DAG_A = (A, T_A, E_A)$ where T_A is the set of GO terms in DAG_A , including term A and all of its ancestor terms in the GO graph, and E_A is the set of edges connecting the GO terms in DAG_A .

- Wang's method

To encode the semantics of a GO term in a measurable format to enable a quantitative comparison between two term's semantics, Wang firstly defined the semantic value of term A as the aggregate contribution of all terms in DAG_A to the semantics of term A, terms closer to term A in DAG_A contribute more to its semantics. Thus, defined the contribution of a GO term t to the semantics of GO term A as the S-value of GO term t related to term A. For any of term t in $DAG_A = (A, T_A, E_A)$, its S-value related to term A. $S_A(t)$ is defined as:

$$\begin{cases} S_A(A) = 1 \\ S_A(t) = \max\{w_e \times S_A(t') | t' \in \text{childrenof}(t)\} \text{ if } t \neq A \end{cases}$$

where w_e is the semantic contribution factor for edge $e \in E_A$ linking term t with its child term t' . Wang defined term A contributes to its own as one. After obtaining the S-values for all terms in DAG_A , the semantic value of GO term A, $SV(A)$, is calculated as:

$$SV(A) = \sum_{t \in T_A} S_A(t)$$

Thus, given two GO terms A and B, the semantic similarity between these two terms, $sim_{Wang}(A, B)$, is defined as:

$$sim_{Wang}(A, B) = \frac{\sum_{t \in T_A \cap T_B} S_A(t) + S_B(t)}{SV(A) + SV(B)}$$

where $S_A(t)$ is the S-value of GO term t related to term A and $S_B(t)$ is the S-value of GO term t related to term B.

This method proposed by Wang (Wang et al., 2007) determines the semantic similarity of two GO terms based on both the locations of these terms in the GO graph and their relations with their ancestor terms.

On the basis of semantic similarity between GO terms, *GOSemSim* can also compute semantic similarity among sets of GO terms, gene products, and gene clusters.

We implemented four methods which called *max*, *avg*, *rcmax*, and *BMA* to combine semantic similarity scores of multiple GO terms. The similarities among gene products and gene clusters which annotated by multiple GO terms were also calculated by the same combine methods mentioned above.

Given two GO terms sets $GO_1 = \{go_{11}, go_{12} \cdots go_{1m}\}$ and $GO_2 = \{go_{21}, go_{22} \cdots go_{2n}\}$ annotated for tow genes g_1 and g_2 , four combine methods for calculating gene similarity are defined as follows:

- The *max* method calculates the maximum semantic similarity score over all pairs of GO terms between these two sets.

$$sim_{max}(g_1, g_2) = \max_{1 \leq i \leq m, 1 \leq j \leq n} sim(go_{1i}, go_{2j})$$

- The *avg* calculate the average semantic similarity score over all pairs of GO terms.

$$sim_{avg}(g_1, g_2) = \frac{\sum_{i=1}^m \sum_{j=1}^n sim(go_{1i}, go_{2j})}{m \times n}$$

- Similarities among GO terms form a matrix, and method *rcmax* use the maximum of RowScore and ColumnScore as the similarity, where RowScore (or ColumnScore) is the average of maximum similarities on each row (or column).

$$sim_{rcmax}(g_1, g_2) = \max\left(\frac{\sum_{i=1}^m \max_{1 \leq j \leq n} sim(go_{1i}, go_{2j})}{m}, \frac{\sum_{j=1}^n \max_{1 \leq i \leq m} sim(go_{1i}, go_{2j})}{n}\right)$$

- The *BMA* method, used the best-match average strategy, calculates the average of all maximum similarities on each row and column, and defined as:

$$sim_{BMA}(g_1, g_2) = \frac{\sum_{i=1}^m \max_{1 \leq j \leq n} sim(go_{1i}, go_{2j}) + \sum_{j=1}^n \max_{1 \leq i \leq m} sim(go_{1i}, go_{2j})}{m+n}$$

4 Examples

GOSemSim implemented multiple functions for calculate semantic similarities:

- *goSim* for calculate semantic similarity between two GO terms.
- *mgoSim* for calculate semantic similarity among multiple GO terms.
- *geneSim* for calculate semantic similarity between two gene products.
- *mgeneSim* for calculate semantic similarity among multiple gene products.
- *clusterSim* for calculate semantic similarity between two gene clusters.
- *mclusterSim* for calculate semantic similarity among multiple gene clusters.

The following example demonstrated the function calls of these function, details about the arguments can refer to the manuals (eg `?geneSim`).

```
> goSim("GO:0004022", "GO:0005515", ont="MF", measure="Wang")
```

```
[1] 0.158
```

```
> go1 = c("GO:0004022", "GO:0004024", "GO:0004174")
```

```
> go2 = c("GO:0009055", "GO:0005515")
```

```
> mgoSim(go1, go2, ont="MF", measure="Wang", combine="BMA")
```

```
[1] 0.192
```

```
> geneSim("241", "251", ont="MF", organism="human", measure="Wang", combine="BMA")
```

```

$geneSim
[1] 0.16

$GO1
[1] "GO:0005515" "GO:0004051" "GO:0047485" "GO:0050544"

$GO2
[1] "GO:0004035"

> mgeneSim(genes=c("835", "5261", "241", "994"), ont="MF", organism="human", measure="Wang")

```

5 Case Study

In Yu et al. (2011), we proposed a method for measuring functional similarity of microRNAs. This method was based on semantic similarity of microRNAs' target genes, and was calculated by *GOSemSim*. We further ana-

lyzed viral microRNAs using this method (Yu et al., 2011) and compared significant KEGG pathways regulated by different viruses' microRNAs using *clusterProfiler* (Yu et al., 2012).

6 Session Information

The version number of R and packages loaded for generating the vignette were:

```
R version 2.15.1 (2012-06-22)
Platform: x86_64-unknown-linux-gnu (64-bit)
