March 24, 2012

---

CMA-package

*Synthesis of microarray-based classification*

---

## Description

The aim of the package is to provide a user-friendly environment for the evaluation of classification methods using gene expression data. A strong focus is on combined variable selection, hyperparameter tuning, evaluation, visualization and comparison of (up to now) 21 classification methods from three main fields: Discriminant Analysis, Neural Networks and Machine Learning. Although the package has been created with the intention to be used for Microarray data, it can as well be used in various ( $p > n$ )-scenarios.

## Details

Package: CMA  
Type: Package  
Version: 1.3.3  
Date: 2009-9-14  
License: GPL (version 2 or later)

Most Important Steps for the workflow are:

1. Generate evaluation datasets using [GenerateLearningsets](#)
2. (Optionally): Perform variable selection using [GeneSelection](#)
3. (Optionally): Perform hyperparameter tuning using [tune](#)
4. Perform [classification](#) using 1.-3.
5. Repeat 2.-4. based on 1. for several methods: [compBoostCMA](#), [dldaCMA](#), [ElasticNetCMA](#), [fdaCMA](#), [flexdaCMA](#), [gbmCMA](#), [knnCMA](#), [ldaCMA](#), [LassoCMA](#), [nnetCMA](#), [pknnCMA](#), [plrCMA](#), [pls\\_ldaCMA](#), [pls\\_lrCMA](#), [pls\\_rfcCMA](#), [pnnCMA](#), [qdaCMA](#), [rfCMA](#), [scdaCMA](#), [shrinkldaCMA](#), [svmCMA](#)
6. Evaluate the results from 5. using [evaluation](#) and make a comparison by calling [compare](#)

ElasticNetCMA-methods

*Classification and variable selection by the ElasticNet*

---

## Description

Zou and Hastie (2004) proposed a combined L1/L2 penalty for regularization and variable selection. The Elastic Net penalty encourages a grouping effect, where strongly correlated predictors tend to be in or out of the model together. The computation is done with the function `glmPath` from the package of the same name.

## Methods

`X = "matrix", y = "numeric", f = "missing"` signature 1

`X = "matrix", y = "factor", f = "missing"` signature 2

`X = "data.frame", y = "missing", f = "formula"` signature 3

`X = "ExpressionSet", y = "character", f = "missing"` signature 4

For references, further argument and output information, consult [ElasticNetCMA](#)

---

ElasticNetCMA

*Classification and variable selection by the ElasticNet*

---

## Description

Zou and Hastie (2004) proposed a combined L1/L2 penalty for regularization and variable selection. The Elastic Net penalty encourages a grouping effect, where strongly correlated predictors tend to be in or out of the model together. The computation is done with the function `glmPath` from the package of the same name.

The method can be used for variable selection alone, s. [GeneSelection](#).

For S4 method information, see `ElasticNetCMA-methods`.

## Usage

```
ElasticNetCMA(X, y, f, learnind, norm.fraction = 0.1, alpha=0.5, models=FALSE, .
```

**Arguments**

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>. <b>note:</b> by default, the predictors are scaled to have unit variance and zero mean. Can be changed by passing <code>standardize = FALSE</code> via the <code>...</code> argument.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• missing, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be missing; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>norm.fraction</code>	L1 Shrinkage intensity, expressed as the fraction of the coefficient L1 norm compared to the maximum possible L1 norm (corresponds to <code>fraction = 1</code> ). Lower values correspond to higher shrinkage. Note that the default (0.1) need not produce good results, i.e. tuning of this parameter is recommended.
<code>alpha</code>	The elasticnet mixing parameter, with $0 < \alpha \leq 1$ . The penalty is defined as $(1-\alpha)/2 \ \beta\ _2^2 + \alpha \ \beta\ _1$ . <code>alpha=1</code> is the lasso penalty; Currently ' <code>alpha&lt;0.01</code> ' not reliable, unless you supply your own <code>lambda</code> sequence
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments passed to the function <code>glm</code> from the package of the same name.

**Value**

An object of class `clvareselectoutput`.

**Note**

For a strongly related method, s. [LassoCMA](#).  
Up to now, this method can only be applied to binary classification.

## Examples

```
### load Golub AML/ALL data
data(golub)
### extract class labels
golubY <- golub[,1]
### extract gene expression
golubX <- as.matrix(golub[,-1])
### select learningset
ratio <- 2/3
set.seed(111)
learnind <- sample(length(golubY), size=floor(ratio*length(golubY)))
### run ElasticNet - penalized logistic regression (no tuning)
result <- ElasticNetCMA(X=golubX, y=golubY, learnind=learnind, norm.fraction = 0.2, alpha)
show(result)
ftable(result)
plot(result)
```

---

GeneSelection-methods

*General method for variable selection with various methods*

---

## Description

Performs gene selection for the following signatures:

## Methods

- X = "matrix", y = "numeric", f = "missing"** signature 1
- X = "matrix", y = "factor", f = "missing"** signature 2
- X = "data.frame", y = "missing", f = "formula"** signature 3
- X = "ExpressionSet", y = "character", f = "missing"** signature 4

For further argument and output information, consult [GeneSelection](#).

GeneSelection

*General method for variable selection with various methods***Description**

For different learning data sets as defined by the argument `learningsets`, this method ranks the genes from the most relevant to the less relevant using one of various 'filter' criteria or provides a sparse collection of variables (Lasso, ElasticNet, Boosting). The results are typically used for variable selection for the classification procedure that follows.

For S4 class information, s. `GeneSelection-methods`.

**Usage**

```
GeneSelection(X, y, f, learningsets, method = c("t.test", "welch.test", "wilcox.test"))
```

**Arguments**

- |                           |  |
|---------------------------|--|
| <code>X</code>            | Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>   |
| <code>y</code>            | Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code>.</li> <li>• missing, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul>   |
| <code>f</code>            | A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.  |
| <code>learningsets</code> | An object of class <code>learningsets</code> . May be missing, then the complete datasets is used as learning set.   |
| <code>method</code>       | A character specifying the method to be used: <ul style="list-style-type: none"> <li><code>t.test</code> two-sample t.test (equal variances for both classes assumed).</li> <li><code>welch.test</code> Welch modification of the t.test (unequal variances for both classes).</li> <li><code>wilcox.test</code> Wilcoxon rank sum test.</li> <li><code>f.test</code> F test belonging to the linear hypothesis that the mean is the same for all classes. Usually used for the multiclass scheme, is equivalent to <code>method = t.test</code> in the two-class case.</li> <li><code>kruskal.test</code> Multi-class generalization of the Wilcoxon rank sum test and the nonparametric pendant to the F test, respectively.</li> <li><code>limma</code> 'Moderated t' statistic for the two-class case and 'moderated F' statistic for the multiclass case, described in Smyth (2003). Requires the package <code>limma</code>.</li> <li><code>rfe</code> One-step Recursive Feature Elimination, based on the Support Vector Machine. The method is described in Guyon et al. (2002). Requires the package <code>e1071</code>. Take care that appropriate hyperparameters are passed by the <code>...</code> argument.</li> <li><code>rf</code> Random Forest Variable Importance Measure. Requires the package <code>randomForest</code></li> </ul> |

	<code>lasso</code>	L1 penalized logistic regression leads to sparsity with respect to the variables used. Calls the function <code>LassoCMA</code> , which requires the package <code>glm</code> . <b>warning:</b> Take care that appropriate hyperparameters are passed by the <code>...</code> argument.
	<code>elasticnet</code>	Penalized logistic regression with both L1 and L2 penalty, claimed by Zhou and Hastie (2004) to select 'variable groups'. Calls the function <code>ElasticNetCMA</code> , which requires the package <code>glm</code> . <b>warning:</b> Take care that appropriate hyperparameters are passed by the <code>...</code> argument.
	<code>boosting</code>	Componentwise boosting (Buehlmann and Yu, 2003) has been shown to mimic the LASSO (Efron et al., 2004; Buehlmann and Yu, 2006). Calls the function <code>compBoostCMA</code> . Take care that appropriate hyperparameters are passed by the <code>...</code> argument.
	<code>golub</code>	The (theoretically unfounded) variable selection criterion used by Golub et al. (1999), s. <code>golub</code> .
	<code>shrinkcat</code>	The correlation-adjusted t-score from Zuber and Strimmer (2009)
<code>scheme</code>		The scheme to be used in the case of a non-binary response. Must be one of "pairwise", "one-vs-all" or "multiclass". The last case only makes sense if <code>method</code> is one of <code>f.test</code> , <code>limma</code> , <code>rf</code> , <code>boosting</code> , which can directly be applied to the multi class case.
<code>trace</code>		Should the progress be traced ? Default is <code>TRUE</code> .
<code>...</code>		Further arguments passed to the function performing variable selection, s. <code>method</code> .

**Value**

An object of class `genesel`.

**Note**

most of the methods described above are only apt for the binary classification case. The only ones that can be used without restriction in the multiclass case are

- `f.test`
- `kruskal.test`
- `rf`
- `boosting`

For the rest, pairwise or one-vs-all schemes are used.

plot(selttest, iter = 1)
```

---

GenerateLearningsets

*Repeated Divisions into learn- and test sets*

---

### Description

Due to very small sample sizes, the classical division learnset/testset does not give accurate information about the classification performance. Therefore, several different divisions should be used and aggregated. The implemented methods are discussed in Braga-Neto and Dougherty (2003) and Molinaro et al. (2005) whose terminology is adopted.

This function is usually the basis for all deeper analyses.

**Usage**

```
GenerateLearningsets(n, y, method = c("LOOCV", "CV", "MCCV", "bootstrap"),
                    fold = NULL, niter = NULL, ntrain = NULL, strat = FALSE)
```

**Arguments**

n	The total number of observations in the available data set. May be missing if y is provided instead.
y	A vector of class labels, either numeric or a factor. <i>Must</i> be given if strat=TRUE or n is not specified.
method	Which kind of scheme should be used to generate divisions into learning sets and test sets ? Can be one of the following: <b>"LOOCV"</b> Leaving-One-Out Cross Validation. <b>"CV"</b> (Ordinary) Cross-Validation. Note that fold must as well be specified. <b>"MCCV"</b> Monte-Carlo Cross Validation, i.e. random divisions into learning sets with ntrain(s.below) observations and tests sets with ntrain observations. <b>"bootstrap"</b> Learning sets are generated by drawing n times with replacement from all observations. Those not drawn not all form the test set.
fold	Gives the number of CV-groups. Used only when method="CV"
niter	Number of iterations (s.details) .
ntrain	Number of observations in the learning sets. Used only when method="MCCV".
strat	Logical. Should stratified sampling be performed, i.e. the proportion of observations from each class in the learning sets be the same as in the whole data set ? Does not apply for method = "LOOCV".

**Details**

- When method="CV", niter gives the number of times the whole CV-procedure is repeated. The output matrix has then foldxniter rows. When method="MCCV" or method="bootstrap", niter is simply the number of considered learning sets.
- Note that method="CV", fold=n is equivalent to method="LOOCV".

**Value**

An object of class `learningsets`

LassoCMA-methods    *L1 penalized logistic regression*

---

## Description

The Lasso (Tibshirani, 1996) is one of the most popular tools for simultaneous shrinkage and variable selection. Recently, Friedman, Hastie and Tibshirani (2008) have developed an algorithm to compute the entire solution path of the Lasso for an arbitrary generalized linear model, implemented in the package `glmnet`. The method can be used for variable selection alone, s. [GeneSelection](#)

## Methods

- X = "matrix", y = "numeric", f = "missing"** signature 1
- X = "matrix", y = "factor", f = "missing"** signature 2
- X = "data.frame", y = "missing", f = "formula"** signature 3
- X = "ExpressionSet", y = "character", f = "missing"** signature 4

For references, further argument and output information, consult [LassoCMA](#).

LassoCMA

*L1 penalized logistic regression***Description**

The Lasso (Tibshirani, 1996) is one of the most popular tools for simultaneous shrinkage and variable selection. Recently, Friedman, Hastie and Tibshirani (2008) have developed an algorithm to compute the entire solution path of the Lasso for an arbitrary generalized linear model, implemented in the package `glmnet`. The method can be used for variable selection alone, s. [GeneSelection](#).

For S4 method information, see `LassoCMA-methods`.

**Usage**

```
LassoCMA(X, y, f, learnind, norm.fraction = 0.1, models=FALSE, ...)
```

**Arguments**

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>. <b>note:</b> by default, the predictors are scaled to have unit variance and zero mean. Can be changed by passing <code>standardize = FALSE</code> via the <code>...</code> argument.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>norm.fraction</code>	L1 Shrinkage intensity, expressed as the fraction of the coefficient L1 norm compared to the maximum possible L1 norm (corresponds to <code>fraction = 1</code> ). Lower values correspond to higher shrinkage. Note that the default (0.1) need not produce good results, i.e. tuning of this parameter is recommended.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments passed to the function <code>glm</code> from the package of the same name.

**Value**

An object of class `clvargseloutput`.

**Note**

For a strongly related method, s. [ElasticNetCMA](#).  
Up to now, this method can only be applied to binary classification.

Planarplot-methods *Visualize Separability of different classes*

---

**Description**

Given two variables, the methods trains a classifier (argument `classifier`) based on these two variables and plots the resulting class regions, learning- and test observations in the plane.

Appropriate variables are usually found by [GeneSelection](#).

## Methods

**X = "matrix", y = "numeric", f = "missing"** signature 1  
**X = "matrix", y = "factor", f = "missing"** signature 2  
**X = "data.frame", y = "missing", f = "formula"** signature 3  
**X = "ExpressionSet", y = "character", f = "missing"** signature 4  
 For further argument and output information, consult [Planarplot](#).

---

 Planarplot

 Visualize Separability of different classes
 

---

## Description

Given two variables, the methods trains a classifier (argument `classifier`) based on these two variables and plots the resulting class regions, learning- and test observations in the plane.

Appropriate variables are usually found by [GeneSelection](#).

For S4 method information, s. [Planarplot-methods](#).

## Usage

```
Planarplot(X, y, f, learnind, predind, classifier, gridsize = 100, ...)
```

## Arguments

X	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
y	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if X is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if X is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul>
f	A two-sided formula, if X is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
learnind	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
predind	A vector containing <i>exactly</i> two indices that denote the two variables used for classification.
classifier	Name of function ending with <code>CMA</code> indicating the classifier to be used.
gridsize	The gridsize used for two-dimensional plotting. For both variables specified in <code>predind</code> , an equidistant grid of size <code>gridsize</code> is created. The resulting two grids are then combined to obtain <code>gridsize^2</code> points in the real plane which are used to draw the class regions. Defaults to 100 which is usually a reasonable choice, but takes some time.
...	Further argument passed to <code>classifier</code> .

**Value**

No return.

---

**Description**

In this package hyperparameter tuning is performed by an inner cross-validation step for each `learningset`. A grid of values is tried and evaluated in terms of the misclassification rate, the results are saved in an object of class `tuningresult`. This method displays (separately for each `learningset`) the hyperparameter/ hyperparameter combination that showed the best results. Note that this must not be unique; in this case, only one combination is displayed.

**Usage**

```
best(object, ...)
```

**Arguments**

`object` An object of class `tuningresult`.  
`...` Currently unused argument.

**Value**

A list with elements equal to the number of different `learningsets`. Each element contains the best hyperparameter combination and the corresponding misclassification rate.

**Author(s)**

Martin Slawski <ms@cs.uni-sb.de>

Anne-Laure Boulesteix <boulesteix@ibe.med.uni-muenchen.de>

tune

---

boxplot

*Make a boxplot of the classifier evaluation*

---

**Description**

This method displays the slot `scores` of performance scores of an object of class `evaloutput`.

**Arguments**

`x` An object of class `evaloutput`.

`...` Further graphical parameters passed to the classical `boxplot` function.

**Value**

The only return is a boxplot.

---

### Description

Perform classification for the following signatures:

### Methods

`X = "matrix", y = "numeric", f = "missing"` signature 1

`X = "matrix", y = "factor", f = "missing"` signature 2

`X = "data.frame", y = "missing", f = "formula"` signature 3

`X = "ExpressionSet", y = "character", f = "missing"` signature 4

For further argument and output information, consult [classification](#).

---

 classification

*General method for classification with various methods*

---

### Description

Most general function in the package, providing an interface to perform variable selection, hyper-parameter tuning and classification in one step. Alternatively, the first two steps can be performed separately and can then be plugged into this function.

For S4 method information, s. [classification-methods](#).

### Usage

```
classification(X, y, f, learningsets, genesel, genesellist = list(), nbgene, cla
```

### Arguments

- |                |  |
|----------------|--|
| <code>X</code> | Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>   |
| <code>y</code> | Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p> |
| <code>f</code> | A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.  |

<code>learningsets</code>	An object of class <code>learningsets</code> . May be missing, then the complete datasets is used as learning set.
<code>genesel</code>	Optional (but usually recommended) object of class <code>genesel</code> containing variable importance information for the argument <code>learningsets</code>
<code>geneselist</code>	In the case that the argument <code>genesel</code> is missing, this is an argument list passed to <code>GeneSelection</code> . If both <code>genesel</code> and <code>geneselist</code> are missing, no variable selection is performed.
<code>nbgene</code>	Number of best genes to be kept for classification, based on either <code>genesel</code> or the call to <code>GeneSelection</code> using <code>geneselist</code> . In the case that both are missing, this argument is not necessary. <b>note:</b> <ul style="list-style-type: none"> <li>• If the gene selection method has been one of "lasso", "elasticnet", "boosting", <code>nbgene</code> will be reset to <code>min(s, nbgene)</code> where <code>s</code> is the number of nonzero coefficients.</li> <li>• if the gene selection scheme has been "one-vs-all", "pairwise" for the multiclass case, there exist several rankings. The top <code>nbgene</code> will be kept of <i>each</i> of them, so the number of effective used genes will sometimes be much larger.</li> </ul>
<code>classifier</code>	Name of function ending with <code>CMA</code> indicating the classifier to be used.
<code>tuneres</code>	Analogous to the argument <code>genesel</code> - object of class <code>tuningresult</code> containing information about the best hyperparameter choice for the argument <code>learningsets</code> .
<code>tuninglist</code>	Analogous to the argument <code>geneselist</code> . In the case that the argument <code>tuneres</code> is missing, this in argument list passed to <code>tune</code> . If both <code>tuneres</code> and <code>tuninglist</code> are missing, no variable selection is performed. <b>warning:</b> Note that if a user-defined hyperparameter grid is passed, this will result in a list within a list: <code>tuninglist = list(grid=list(argname = c()), s. example. <b>warning:</b> Contrary to <code>tune</code>, if <code>tuninglist</code> is an empty list (default), no hyperparameter tuning will be performed at all. To use pre-defined hyperparameter grids, the argument is <code>tuninglist = list(grid = list())</code>.</code>
<code>trace</code>	Should progress be traced ? Default is <code>TRUE</code> .
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments passed to the function <code>classifier</code> .

### Details

For details about hyperparameter tuning, consult `tune`.

### Value

A list of objects of class `cloutput` and `clvarseloutput`, respectively; its length equals the number of different `learningsets`. The single elements of the list can conveniently be combined using the `join` function. The results can be analyzed and evaluated by various measures using the method `evaluation`.

## End(Not run)
```

---

cloutput-class      "*cloutput*"

---

## Description

Object returned by one of the classifiers (functions ending with CMA)

**Slots**

**learnind:** Vector of indices that indicates which observations were used in the learning set.

**y:** Actual (true) class labels of predicted observations.

**yhat:** Predicted class labels by the classifier.

**prob:** A numeric matrix whose rows equals the number of predicted observations (length of `y/yhat`) and whose columns equal the number of different classes in the learning set. Rows add up to one. Entry `j, k` of this matrix contains the probability for the `j`-th predicted observation to belong to class `k`. Can be a matrix of NAs, if the classifier used does not provide any probabilities

**method:** Name of the classifier used.

**mode:** character, one of "binary" (if the number of classes in the learning set is two) or `multiclass` (if it is more than two).

**model:** List containing the constructed classifiers.

**Methods**

**show** Use `show(cloutput-object)` for brief information

**ftable** Use `ftable(cloutput-object)` to obtain a confusion matrix/cross-tabulation of `y` vs. `yhat`, s. [ftable, cloutput-method](#).

**plot** Use `plot(cloutput-object)` to generate a probability plot of the matrix `prob` described above, s. [plot, cloutput-method](#)

**roc** Use `roc(cloutput-object)` to compute the empirical ROC curve and the Area Under the Curve (AUC) based on the predicted probabilities, s. [roc, cloutput-method](#)

**Author(s)**

Martin Slawski <ms@cs.uni-sb.de>

Anne-Laure Boulesteix <boulesteix@ibe.med.uni-muenchen.de>

**See Also**

---

`clvarelooutput-class`

*"clvarelooutput"*

---

**Description**

Object returned by all classifiers that can perform variable selection or compute variable importance. These are:

- Random Forest, s. [rfCMA](#),
- Componentwise Boosting, s. [compBoostCMA](#),
- LASSO-logistic regression, s. [LassoCMA](#),
- ElasticNet-logistic regression, s. [ElasticNetCMA](#)

. Objects of class `clvarelooutput` extend both the class `cloutput` and `varsel`, s. [below](#).

**Slots**

**learnind:** Vector of indices that indicates which observations were used in the learning set.

**y:** Actual (true) class labels of predicted observations.

**yhat:** Predicted class labels by the classifier.

**prob:** A numeric matrix whose rows equals the number of predicted observations (length of `y/yhat`) and whose columns equal the number of different classes in the learning set. Rows add up to one. Entry `j, k` of this matrix contains the probability for the `j`-th predicted observation to belong to class `k`. Can be a matrix of NAs, if the classifier used does not provide any probabilities

**method:** Name of the classifier used.

**mode:** character, one of "binary" (if the number of classes in the learning set is two) or "multiclass" (if it is more than two).

**varels:** numeric vector of variable importance measures (for Random Forest) or absolute values of regression coefficients (for the other three methods mentioned above) (from which the majority will be zero).

**Extends**

Class "`cloutput`", directly. Class "`varelooutput`", directly.

**Methods**

**show** Use `show(cloutput-object)` for brief information

**ftable** Use `ftable(cloutput-object)` to obtain a confusion matrix/cross-tabulation of `y` vs. `yhat`, s. [ftable, cloutput-method](#).

**plot** Use `plot(cloutput-object)` to generate a probability plot of the matrix `prob` described above, s. [plot, cloutput-method](#)

**roc** Use `roc(cloutput-object)` to compute the empirical ROC curve and the Area Under the Curve (AUC) based on the predicted probabilities, s. [roc, cloutput-method](#)

 compBoostCMA-methods

*Componentwise Boosting*

---

**Description**

Roughly speaking, Boosting combines 'weak learners' in a weighted manner in a stronger ensemble.

'Weak learners' here consist of linear functions in one component (variable), as proposed by Buehlmann and Yu (2003).

It also generates sparsity and can as well be as used for variable selection alone. (s. [GeneSelection](#).)

**Methods**

**X = "matrix", y = "numeric", f = "missing"** signature 1

**X = "matrix", y = "factor", f = "missing"** signature 2

**X = "data.frame", y = "missing", f = "formula"** signature 3

**X = "ExpressionSet", y = "character", f = "missing"** signature 4

For further argument and output information, consult [compBoostCMA](#).

---

 compBoostCMA

*Componentwise Boosting*

---

**Description**

Roughly speaking, Boosting combines 'weak learners' in a weighted manner in a stronger ensemble.

'Weak learners' here consist of linear functions in one component (variable), as proposed by Buehlmann and Yu (2003).

It also generates sparsity and can as well be as used for variable selection alone. (s. [GeneSelection](#)).

For S4 method information, see [compBoostCMA-methods](#).

**Usage**

```
compBoostCMA(X, y, f, learnind, loss = c("binomial", "exp", "quadratic"), mstop
```

**Arguments**

- |   |  |
|---|--|
| X | Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul> |
| y | Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> </ul>  |

- A character if `X` is an `ExpressionSet` that specifies the phenotype variable.
- `missing`, if `X` is a `data.frame` and a proper formula `f` is provided.

**WARNING:** The class labels will be re-coded to range from 0 to  $K-1$ , where  $K$  is the total number of different classes in the learning set.

<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>loss</code>	Character specifying the loss function - one of "binomial" (LogitBoost), "exp" (AdaBoost), "quadratic"(L2Boost).
<code>mstop</code>	Number of boosting iterations, i.e. number of updates to perform. The default (100) does not necessarily produce good results, therefore usage of <code>tune</code> for this argument is highly recommended.
<code>nu</code>	Shrinkage factor applied to the update steps, defaults to 0.1. In most cases, it suffices to set <code>nu</code> to a very low value and to concentrate on the optimization of <code>mstop</code> .
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Currently unused arguments.

### Details

The method is partly based on code from the package `mboost` from T. Hothorn and P. Buehlmann. The algorithm for the multiclass case is described in Lutz and Buehlmann (2006) as 'rowwise updating'.

### Value

An object of class `clvarseloutput`.

### Author(s)

Martin Slawski <ms@cs.uni-sb.de>

compare-methods

*Compare different classifiers*

---

**Description**

Compare different classifiers for the following signatures:

**Methods**

**clresultlist = "list"** signature 1

For further argument and output information, consult [compare](#)

compare

*Compare different classifiers***Description**

Classifiers can be evaluated separately using the method `evaluation`. Normally, several classifiers are used for the same dataset and their performance is compared. This comparison procedure is essentially facilitated by this method. For S4 method information, s. `compare-methods`

**Usage**

```
compare(clresultlist, measure = c("misclassification", "sensitivity",
  "specificity", "average probability", "brier score", "auc"), aggfun =
  meanrm, plot = FALSE, ...)
```

**Arguments**

- `clresultlist` A list of lists (!) of objects of class `cloutput` or `clvarseloutput`. Each inner list is usually returned by `classification`. Additionally, the different list elements of the outer list should have been created by different classifiers, s. also example below.
- `measure` A character vector containing one or more of the elements listed below. By default, all measures are computed, using `evaluation` with `scheme = "iterationwise"`. Note that "sensitivity", "specificity", "auc" cannot be computed for the multiclass case.
- "misclassification" The missclassification rate.
  - "sensitivity" The sensitivity or 1-false negative rate. Can only be computed for binary classification.
  - "specificity" The specificity or 1-false positive rate. Can only be computed for binary classification.
  - "average probability" The average probability assigned to the correct class. Requirement is that the used classifier provides probability estimations. The optimum performance is 1.
  - "brier score" The Brier Score is generally defined as  $\langle \text{sum over all observation } i \rangle \langle \text{sum over all classes } k \rangle (I(y_i=k) - P(k))^2$ , with  $I()$  denoting the indicator function and  $P(k)$  the estimated probability for class  $k$ . The optimum performance is 0.
  - "auc" The Area under the Curve (AUC) belonging to the empirical ROC curve computed from the estimated probabilities and the true class labels. Can only be computed for binary classification and if "scheme = iterationwise", s. below. S. also `roc`, `cloutput-method`.
- `aggfun` Function that determines how performance among different iterations are aggregated. Default is `meanrm`, which computes the mean using `na.rm=T`. Other possible choices are quantiles.
- `plot` Should the performance of different classifiers be visualized by a joint boxplot? Default is `FALSE`.
- `...` Further arguments passed to `boxplot` in the case that `plot = TRUE`.

**Value**

A `data.frame` with rows corresponding to the compared classifiers and columns to the performance measures, aggregated by `aggfun`, s. above.

**Note**

If more than one measure is computed and `plot = TRUE`, one separate plot is created for each of them.

For further argument and output information, consult [dldaCMA](#).

---

dldaCMA      *Diagonal Discriminant Analysis*

---

### Description

Performs a diagonal discriminant analysis under the assumption of a multivariate normal distribution in each classes (with equal, diagonally structured) covariance matrices. The method is also known under the name 'naive Bayes' classifier.

For S4 method information, see [dldaCMA-methods](#).

### Usage

```
dldaCMA(X, y, f, learnind, models=FALSE, ...)
```

### Arguments

- |   |   |
|---|---|
| X | Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>                    |
| y | Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if X is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if X is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> |

**WARNING:** The class labels will be re-coded to range from 0 to  $K-1$ , where  $K$  is the total number of different classes in the learning set.

<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be missing; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Currently unused argument.

**Value**

An object of class `cloutput`.

**Note**

As opposed to linear or quadratic discriminant analysis, variable selection is not strictly necessary.

---

```
evaloutput-class    "evaloutput"
```

---

## Description

Object returned by the method [evaluation](#).

## Slots

**score:** A numeric vector of performance scores whose length depends on "scheme", s.below. It equals the number of iterations (number of different datasets) if "scheme = iterationwise" and the number of all observations in the complete dataset otherwise. As not necessarily all observation must be predicted at least one time, score can also contain NAs for those observations not classified at all.

**measure:** performance measure used, s. [evaluation](#).

**scheme:** scheme used, s. [evaluation](#)

**method:** name of the classifier that has been evaluated.

## Methods

**show** Use `show(evaloutput-object)` for brief information.

**summary** Use `summary(evaloutput-object)` to apply the classic `summary()` function to the slot `score`, s. [summary](#), [evaloutput-method](#)

**boxplot** Use `boxplot(evaloutput-object)` to display a boxplot of the slot `score`, s. [boxplot](#), [evaloutput-method](#).

**obsinfo** Use `obsinfo(evaloutput-object, threshold)` to display all observations consistently correctly or incorrectly classified (depending on the value of the argument `threshold`), s. [obsinfo](#).

---

evaluation *Evaluation of classifiers*

---

### Description

The performance of classifiers can be evaluated by six different measures and two different schemes that are described more precisely below.

For S4 method information, s. [evaluation-methods](#).

### Usage

```
evaluation(clresult, cltrain = NULL, cost = NULL, y = NULL, measure = c("misclas",
                                "sensitivity", "specificity"),
           scheme = c("iterationwise", "observationwise", "classwise"))
```

### Arguments

<code>clresult</code>	A list of objects of class <code>cloutput</code> or <code>clvarseloutput</code>
<code>cltrain</code>	An object of class <code>cloutput</code> in which the <i>whole</i> dataset was used as learning set. Only used if <code>method = "0.632"</code> or <code>method = "0.632+"</code> in order to obtain an estimation for the resubstitution error rate.
<code>cost</code>	An optional cost matrix used if <code>measure = "misclassification"</code> . If it is not specified (default), the cost is the usual indicator loss. Otherwise, entry $i, j$ of <code>cost</code> quantifies the loss when the true class is class $i-1$ and the predicted class is $j-1$ , provided the conventional coding $0, \dots, K-1$ in the case of $K$ classes is used. Usually, the matrix contains only non-negative entries with zeros on the diagonal, but this is not obligatory. Make sure that the dimension of the matrix matches the number of classes.
<code>y</code>	A vector containing the true class labels. Only needed if <code>scheme = "classwise"</code> .
<code>measure</code>	Performance measure to be used: "misclassification" The missclassification rate. "sensitivity" The sensitivity or 1-false negative rate. Can only be computed for binary classification. "specificity" The specificity or 1-false positive rate. Can only be computed for binary classification.

	"average probability" The average probability assigned to the correct class. Requirement is that the used classifier provides probability estimations. The optimum performance is 1.
	"brier score" The Brier Score is generally defined as $\langle \text{sum over all observation } i \rangle \langle \text{sum over all classes } k \rangle (I(y_{i=k}) - P(k))^2$ , with $I()$ denoting the indicator function and $P(k)$ the estimated probability for class $k$ . The optimum performance is 0.
	"auc" The Area under the Curve (AUC) belonging to the empirical ROC curve computed from the estimated probabilities and the true class labels. Can only be computed for binary classification and if "scheme = iterationwise", s. below. S. also <code>roc</code> , <code>cloutput-method</code> .
	"0.632" The 0.632 estimator (s. reference) for the misclassification rate (applied iteration- or) observationwise, if bootstrap learning sets have been used. Note that <code>cltrain</code> must be provided.
	"0.632+" The 0.632+ estimator (s. reference) for the misclassification rate (applied iteration- or) observationwise, if bootstrap learning sets have been used. Note that <code>cltrain</code> must be provided.
scheme	"iterationwise" The performance measures listed above are computed for each different iteration, i.e. each different <code>learningset</code>
	"observationwise" The performance measures listed above (except for "auc") are computed separately for each observation classified one or several times, depending on the <code>learningset</code> scheme.
	"classwise" The performance measures (exceptions: "auc", "0.632", "0.632+") are computed separately for each class, averaged over both iterations and observations.

### Value

An object of class `evaloutput`.

```

## Description

Fisher's Linear Discriminant Analysis constructs a subspace of 'optimal projections' in which classification is performed. The directions of optimal projections are computed by the function `cancor` from the package `stats`. For an exhaustive treatment, see e.g. Ripley (1996).

## Methods

**X = "matrix", y = "numeric", f = "missing"** signature 1

**X = "matrix", y = "factor", f = "missing"** signature 2

**X = "data.frame", y = "missing", f = "formula"** signature 3

**X = "ExpressionSet", y = "character", f = "missing"** signature 4

For references, further argument and output information, consult [fdaCMA](#).

fdaCMA

*Fisher's Linear Discriminant Analysis***Description**

Fisher's Linear Discriminant Analysis constructs a subspace of 'optimal projections' in which classification is performed. The directions of optimal projections are computed by the function `cancor` from the package `stats`. For an exhaustive treatment, see e.g. Ripley (1996).

For S4 method information, see [fdaCMA-methods](#).

**Usage**

```
fdaCMA(X, y, f, learnind, comp = 1, plot = FALSE, models=FALSE)
```

**Arguments**

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A <code>factor</code>.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided. <b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</li> </ul>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>comp</code>	Number of discriminant coordinates (projections) to compute. Default is one, must be smaller than or equal to $K-1$ , where $K$ is the number of classes.
<code>plot</code>	Should the projections onto the space spanned by the optimal projection directions be plotted? Default is <code>FALSE</code> .
<code>models</code>	a logical value indicating whether the model object shall be returned

**Value**

An object of class `cloutput`.

**Note**

Excessive variable selection has usually to performed before `fdaCMA` can be applied in the  $p > n$  setting. Not reducing the number of variables can result in an error message.

 flexdaCMA-methods

*Flexible Discriminant Analysis*

---

**Description**

This method is experimental.

It is easy to show that, after appropriate scaling of the predictor matrix  $X$ , Fisher's Linear Discriminant Analysis is equivalent to Discriminant Analysis in the space of the fitted values from the linear regression of the  $n_{\text{learn}} \times K$  indicator matrix of the class labels on  $X$ . This gives rise to 'non-linear discriminant analysis' methods that expand  $X$  in a suitable, more flexible basis. In order to avoid overfitting, penalization is used. In the implemented version, the linear model is replaced by a generalized additive one, using the package `mgcv`.

## Methods

`X = "matrix", y = "numeric", f = "missing"` signature 1  
`X = "matrix", y = "factor", f = "missing"` signature 2  
`X = "data.frame", y = "missing", f = "formula"` signature 3

 flexdaCMA

*Flexible Discriminant Analysis*

---

## Description

This method is experimental.

It is easy to show that, after appropriate scaling of the predictor matrix  $X$ , Fisher's Linear Discriminant Analysis is equivalent to Discriminant Analysis in the space of the fitted values from the linear regression of the  $n_{\text{learn}} \times K$  indicator matrix of the class labels on  $X$ . This gives rise to 'non-linear discriminant analysis' methods that expand  $X$  in a suitable, more flexible basis. In order to avoid overfitting, penalization is used. In the implemented version, the linear model is replaced by a generalized additive one, using the package `mgcv`.

For S4 method information, s. [flexdaCMA-methods](#).

## Usage

```
flexdaCMA(X, y, f, learnind, comp = 1, plot = FALSE, models=FALSE, ...)
```

## Arguments

<code>X</code>	<p>Gene expression data. Can be one of the following:</p> <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	<p>Class labels. Can be one of the following:</p> <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>comp</code>	Number of discriminant coordinates (projections) to compute. Default is one, must be smaller than or equal to $K-1$ , where $K$ is the number of classes.

plot	Should the projections onto the space spanned by the optimal projection directions be plotted ? Default is FALSE.
models	a logical value indicating whether the model object shall be returned
...	Further arguments passed to the function <code>gam</code> from the package <code>mgcv</code> .

**Value**

An object of class `cloutput`.

**Note**

Excessive variable selection has usually to performed before `flexdaCMA` can be applied in the `p > n` setting. Recall that the original predictor dimension is even enlarged, therefore, it should be applied only with very few variables.

learnind <- sample(length(golubY), size=floor(ratio*length(golubY)))
### run flexible Discriminant Analysis
result <- flexdaCMA(X=golubX, y=golubY, learnind=learnind, comp = 1)
### show results
show(result)
ftable(result)
plot(result)
```

---

 ftable

*Cross-tabulation of predicted and true class labels*

---

**Description**

An object of class `cloutput` contains (among others) the slot `y` and `yhat`. The former contains the true, the last the predicted class labels. Both are cross-tabulated in order to obtain a so-called confusion matrix. Counts out of the diagonal are misclassifications.

**Arguments**

`x` An object of class `cloutput`  
`...` Currently unused argument.

**Value**

No return.

 gbmCMA-methods

*Tree-based Gradient Boosting*

---

**Description**

Roughly speaking, Boosting combines 'weak learners' in a weighted manner in a stronger ensemble. This method calls the function `gbm.fit` from the package `gbm`. The 'weak learners' are simple trees that need only very few splits (default: 1).

**Methods**

`X = "matrix", y = "numeric", f = "missing"` signature 1  
`X = "matrix", y = "factor", f = "missing"` signature 2  
`X = "data.frame", y = "missing", f = "formula"` signature 3  
`X = "ExpressionSet", y = "character", f = "missing"` signature 4  
 For further argument and output information, consult [gbmCMA](#).

gbmCMA

*Tree-based Gradient Boosting***Description**

Roughly speaking, Boosting combines 'weak learners' in a weighted manner in a stronger ensemble. This method calls the function `gbm.fit` from the package `gbm`. The 'weak learners' are simple trees that need only very few splits (default: 1).

For S4 method information, see [gbmCMA-methods](#).

**Usage**

```
gbmCMA(X, y, f, learnind, models=FALSE, ...)
```

**Arguments**

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• missing, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be missing; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments passed to the function <code>gbm.fit</code> from the package of the same name. Worth mentioning are <ul style="list-style-type: none"> <li><code>ntrees</code> Number of trees to fit (size of the ensemble), defaults to 100. This parameter should be optimized using <a href="#">tune</a>.</li> <li><code>shrinkage</code> The learning rate (default is 0.001). Usually fixed to a very low value.</li> <li><code>distribution</code> Loss function to be used. Default is "bernoulli", i.e. <code>LogitBoost</code>, a (less robust) alternative is "adaboost".</li> <li><code>interaction.depth</code> Number of splits used by the 'weak learner' (single decision tree). Default is 1.</li> </ul>

**Value**

An object of class `cloutput`.

**Note**

Up to now, this method can only be applied to binary classification.

genesel-class

"genesel"

---

**Description**

Object returned from a call to [GeneSelection](#)

### Slots

**rankings:** A list of matrices. For the two-class case and the multi-class case where a genuine multi-class method has been used for variable selection, the length of the list is one. Otherwise, it is named according to the different binary scenarios (e.g. 1 vs 3). Each list element is a matrix with rows corresponding to iterations (different `learningsets`) and columns to variables. Each row thus contains an index vector representing the order of the variables with respect to their variable importance (s. `slot importance`)

**importance:** A list of matrices, with the same structure as described for the slot `rankings`. Each row of these matrices are ordered according to `rankings` and contain the variable importance measure (absolute value of test statistic or regression coefficient).

**method:** Name of the method used for variable selection, s. [GeneSelection](#).

**scheme:** The scheme used in the case of a non-binary response, one of "pairwise", "one-vs-all" or "multiclass".

### Methods

**show** Use `show(genesel-object)` for brief information

**toplist** Use `toplist(genesel-object, k=10, iter = 1)` to display the top first 10 variables and their variable importance for the first iteration (first `learningset`), s. [toplist](#).

**plot** Use `plot(genesel-object, k=10, iter=1)` to display a barplot of the variable importance of the top first 10 variables, s. [plot, genesel-method](#)

`internals`

*Internal functions*

---

**Description**

Not intended to be called directly by the user.

---

`join-methods`

*Combine list elements returned by the method classification*

---

**Description**

The list of objects of class `cloutput` can be unified into one object for the following signatures:

**Methods**

`cloutputlist = "list"` signature 1

For further argument and output information, consult `join`.

---

`join`*Combine list elements returned by the method classification*

---

**Description**

The method `classification` returns a list of class `cloutput` or `clvarseloutput`. It is often more convenient to work with an object of class `cloutput` instead with a whole list, e.g. because the convenience method defined for that class can be used.

For S4 method information, s. [join-methods](#)

**Usage**

```
join(cloutputlist)
```

**Arguments**

`cloutputlist` A list of objects of classes `cloutput` or `clvarseloutput`, usually that returned by a call to the method `classification`. The only requirement for a succesful join is that the used dataset and classifier are the same for each list element.

**Value**

An object of class `cloutput`. **warning:**If the elements of `cloutputlist` have originally been of class `clvarseloutput`, the slot `varsel` will be dropped !

**Note**

The result of the `join` method is incompatible with the methods `evaluation`, `compare`. These require the lists returned by `classification`.

 For S4 method information, see [knnCMA-methods](#).

### Usage

```
knnCMA(X, y, f, learnind, models=FALSE, ...)
```

### Arguments

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. Must not be missing for this method.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments to be passed to <code>knn</code> from the package <code>class</code> , in particular the number of nearest neighbours to use (argument <code>k</code> ).

### Value

An object of class `cloutput`.

### Note

Class probabilities are *not* returned. For a probabilistic variant of `knn`, s. [pknnCMA](#).

set.seed(111)
learnind <- sample(length(khanY), size=floor(ratio*length(khanY)))
### run knn
result <- knnCMA(X=khanX, y=khanY, learnind=learnind, k = 5)
### show results
show(result)
ftable(result)
```

## Description

Performs a linear discriminant analysis for the following signatures:

**Methods**

`X = "matrix", y = "numeric", f = "missing"` signature 1  
`X = "matrix", y = "factor", f = "missing"` signature 2  
`X = "data.frame", y = "missing", f = "formula"` signature 3  
`X = "ExpressionSet", y = "character", f = "missing"` signature 4  
 For further argument and output information, consult [ldaCMA](#).

ldaCMA

*Linear Discriminant Analysis***Description**

Performs a linear discriminant analysis under the assumption of a multivariate normal distribution in each classes (with equal, but generally structured) covariance matrices. The function `lda` from the package `MASS` is called for computation.

For S4 method information, see [ldaCMA-methods](#).

**Usage**

```
ldaCMA(X, y, f, learnind, models=FALSE, ...)
```

**Arguments**

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments to be passed to <code>lda</code> from the package <code>MASS</code>

**Value**

An object of class `cloutput`.

**Note**

Excessive variable selection has usually to be performed before ldaCMA can be applied in the  $p > n$  setting. Not reducing the number of variables can result in an error message.

show(ldaresult)
ftable(ldaresult)
plot(ldaresult)
```

---

```
learningsets-class "learningsets"
```

---

### Description

An object returned from `GenerateLearningsets` which is usually passed as arguments to `GeneSelection`, `tune` and `classification`.

### Slots

`learnmatrix`: A matrix of dimension `niter` x `ntrain`. Each row contains the indices of those observations representing the learningset for one iteration. If `method = CV`, zeros appear due to rounding issues.

`method`: The method used to generate the `learnmatrix`, s.`GenerateLearningsets`

`ntrain`: Number of observations in one learning set. If `method = CV`, this number is not attained for all iterations, due to rounding issues.

`iter`: Number of iterations (different learningsets) that are stored in `learnmatrix`.

### Methods

- `show` Use `show(learningsets-object)` for brief information.

### Author(s)

Martin Slawski <ms@cs.uni-sb.de>

Anne-Laure Boulesteix <boulesteix@ibe.med.uni-muenchen.de>

Christoph Bernau <bernau@ibe.med.uni-muenchen.de>

For further argument and output information, consult [nnetCMA](#).

nnetCMA

*Feed-forward Neural Networks***Description**

This method provides access to the function `nnet` in the package of the same name that trains Feed-forward Neural Networks with one hidden layer.  
For S4 method information, see [nnetCMA-methods](#)

**Usage**

```
nnetCMA(X, y, f, learnind, eigengenes = FALSE, models=FALSE, ...)
```

**Arguments**

- |            |  |
|------------|--|
| X          | Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>   |
| y          | Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if X is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if X is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p> |
| f          | A two-sided formula, if X is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.   |
| learnind   | An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.   |
| eigengenes | Should the training be performed be in the space of eigengenes obtained from a singular value decomposition of the Gene expression data matrix ? Default is <code>FALSE</code> ; in this case, variable selection is necessary to reduce the number of weights that have to be optimized.  |
| models     | a logical value indicating whether the model object shall be returned  |
| ...        | Further arguments passed to the function <code>nnet</code> from the package of the same name.<br>Important parameters are: <ul style="list-style-type: none"> <li>• "size", i.e. the number of units in the hidden layer</li> <li>• "decay" for weight decay.</li> </ul>   |

**Value**

An object of class `cloutput`.

**Note**

- Excessive variable selection is usually necessary if `eigengenes = FALSE`
- Different runs of this method on the same dataset not necessarily produce the same results due to the fact that optimization for Feed-Forward Neural Networks is rather difficult and depends on the choice of (normally randomly chosen) starting values for the network weights.

                    size = 3, decay = 0.01)

### show results
show(nnetresult)
ftable(nnetresult)
plot(nnetresult)
```

---

`obsinfo`*Classifiability of observations*

---

### Description

Some observations are harder to classify than others. It is frequently of interest to know which observations are consistently misclassified; these are candidates for outliers or wrong class labels.

### Arguments

<code>object</code>	An object of class <code>evaluation</code> , generated with <code>scheme = "observationwise"</code>
<code>threshold</code>	threshold value of (observation-wise) performance measure, s. <code>evaluation</code> that has to be exceeded in order to speak of consistent misclassification. If <code>measure = "average probability"</code> , then values <i>below</i> <code>threshold</code> are regarded as consistent misclassification. Note that the default values 1 is not sensible in that case
<code>show</code>	Should the information be printed ? Default is TRUE.

### Details

As not all observation must have been classified at least once, observations not classified at all are also shown.

### Value

A list with two components

`misclassification`

A `data.frame` containing the indices of consistently misclassified observations and the corresponding performance measure.

`notclassified`

The indices of those observations not classified at all, s. details.

---

pknnCMA-methods      *Probabilistic nearest neighbours*

---

### Description

Nearest neighbour variant that replaces the simple voting scheme by a weighted one (based on euclidean distances). This is also used to compute class probabilities.

### Methods

**X = "matrix", y = "numeric", f = "missing"** signature 1

**X = "matrix", y = "factor", f = "missing"** signature 2

**X = "data.frame", y = "missing", f = "formula"** signature 3

**X = "ExpressionSet", y = "character", f = "missing"** signature 4

For further argument and output information, consult [pknnCMA](#).

---

pknnCMA      *Probabilistic Nearest Neighbours*

---

### Description

Nearest neighbour variant that replaces the simple voting scheme by a weighted one (based on euclidean distances). This is also used to compute class probabilities.

For S4 class information, see [pknnCMA-methods](#).

### Usage

```
pknnCMA(X, y, f, learnind, beta = 1, k = 1, models=FALSE, ...)
```

### Arguments

- |   |  |
|---|--|
| X | Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>   |
| y | Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if X is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if X is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p> |
| f | A two-sided formula, if X is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.   |

learnind	An index vector specifying the observations that belong to the learning set. Must not be missing for this method.
beta	Slope parameter for the logistic function which is used for the computation of class probabilities. The default value (1) need not produce reasonable results and can produce warnings.
k	Number of nearest neighbours to use.
models	a logical value indicating whether the model object shall be returned
...	Currently unused argument.

### Details

The algorithm is as follows:

- Determine the  $k$  nearest neighbours
- For each class represented among these, compute the average euclidean distance.
- The negative distances are plugged into the logistic function with parameter  $\beta$ .
- Classify into the class with highest probability.

### Value

An object of class `cloutput`.

### select learningset
ratio <- 2/3
set.seed(111)
learnind <- sample(length(golubY), size=floor(ratio*length(golubY)))
### run probabilistic k-nearest neighbours
result <- pknnCMA(X=golubX, y=golubY, learnind=learnind, k = 3)
### show results
show(result)
ftable(result)
plot(result)
```

---

`plot`*Probability plot*

---

**Description**

A popular way of visualizing the output of classifier is to plot, separately for each class, the predicted probability of each predicted observations for the respective class. For this purpose, the plot area is divided into  $K$  parts, where  $K$  is the number of classes. Predicted observations are assigned, according to their true class, to one of those parts. Then, for each part and each predicted observation, the predicted probabilities are plotted, displayed by coloured dots, where each colour corresponds to one class.

**Arguments**

<code>x</code>	An object of class <code>cloutput</code> whose slot <code>probmatrix</code> does not contain any missing value, i.e. probability estimations are provided by the classifier.
<code>main</code>	A title for the plot (character).

**Value**

No return.

**Note**

The plot usually only makes sense if a sufficiently large numbers of observations has been classified. This is usually achieved by running the classifier on several `learningsets` with the method `classification`. The output can then be processed via `join` to obtain an object of class `cloutput` to which this method can be applied.

`cloutput`

---

Barplot

*Barplot of variable importance*

---

### Description

This method can be seen as a visual pendant to `toplist`. The plot visualizes variable importance by a barplot. The height of the barplots correspond to variable importance. What variable importance exactly means depends on the method chosen when calling `GeneSelection`, s. `genesel`.

### Arguments

<code>x</code>	An object of class <code>genesel</code>
<code>top</code>	Number of top genes whose variable importance should be displayed. Defaults to 10.
<code>iter</code>	Iteration number ( <code>learningset</code> ) for which variable importance should be displayed.
<code>...</code>	Further graphical options passed to <code>barplot</code> .

### Value

No return.

### Note

Note the following

- If `scheme = "multiclass"`, only one plot will be made. Otherwise, one plot will be made for each binary scenario (depending on whether `"scheme"` is `"one-vs-all"` or `"pairwise"`).
- Variable importance do not make sense for variable selection (ranking) methods that are essentially discrete, such as the Wilcoxon-Rank sum statistic or the Kruskal-Wallis statistic.
- For the methods `"lasso"`, `"elasticnet"`, `"boosting"` the number of nonzero coefficients can be very small, resulting in bars of height zero if `top` has been chosen too large.

### Author(s)

Martin Slawski <ms@cs.uni-sb.de>

Anne-Laure Boulesteix <boulesteix@ibe.med.uni-muenchen.de>

`genesel`, `GeneSelection`, `toplist`

---

plot tuningresult *Visualize results of tuning*

---

### Description

After hyperparameter tuning using `tune` it is useful to see which choice of hyperparameters is suitable and how good the performance is.

### Arguments

<code>x</code>	An object of class <code>tuningresult</code> .
<code>iter</code>	Iteration number ( <code>learningset</code> ) for which tuning results should be displayed.
<code>which</code>	Character vector (maximum length is two) naming the arguments for which tuning results should be display. Default is <code>NULL</code> ; if the number of tuned hyperparameter is less or equal than two, then the results for these hyperparameters will be plotted. If this number is two, then a <code>contour</code> plot will be made, otherwise a simple line segment plot. If the number of tuned hyperparameters exceeds two, then <code>which</code> may not be <code>NULL</code> .
<code>...</code>	Further graphical options passed either to <code>plot</code> or <code>contour</code> .

### Value

no return.

### Note

Frequently, several hyperparameter (combinations) perform "best", s. also the remark in `best`.

### Author(s)

pls\_ldaCMA-methods *Partial Least Squares combined with Linear Discriminant Analysis*

---

### Description

-This method constructs a classifier that extracts Partial Least Squares components that are plugged into Linear Discriminant Analysis. The Partial Least Squares components are computed by the package `pls-genomics`.

### Methods

**X = "matrix", y = "numeric", f = "missing"** signature 1

**X = "matrix", y = "factor", f = "missing"** signature 2

**X = "data.frame", y = "missing", f = "formula"** signature 3

**X = "ExpressionSet", y = "character", f = "missing"** signature 4

For further argument and output information, consult [pls\\_ldaCMA](#).

---

pls\_ldaCMA *Partial Least Squares combined with Linear Discriminant Analysis*

---

### Description

This method constructs a classifier that extracts Partial Least Squares components that are plugged into Linear Discriminant Analysis. The Partial Least Squares components are computed by the package `pls-genomics`.

For S4 method information, see [pls\\_ldaCMA-methods](#).

### Usage

```
pls_ldaCMA(X, y, f, learnind, comp = 2, plot = FALSE, models=FALSE)
```

**Arguments**

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>comp</code>	Number of Partial Least Squares components to extract. Default is 2 which can be suboptimal, depending on the particular dataset. Can be optimized using <a href="#">tune</a> .
<code>plot</code>	If <code>comp</code> $\leq$ 2, should the classification space of the Partial Least Squares components be plotted? Default is <code>FALSE</code> .
<code>models</code>	a logical value indicating whether the model object shall be returned

**Value**

An object of class `cloutput`.

pls\_lrCMA *Partial Least Squares followed by logistic regression*

---

**Description**

This method constructs a classifier that extracts Partial Least Squares components that form the the covariates in a binary logistic regression model. The Partial Least Squares components are computed by the package `plsgenomics`.

For S4 method information, see [pls\\_lrCMA-methods](#).

**Usage**

```
pls_lrCMA(X, y, f, learnind, comp = 2, lambda = 1e-4, plot = FALSE, models=FALSE)
```

**Arguments**

<code>x</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>comp</code>	Number of Partial Least Squares components to extract. Default is 2 which can be suboptimal, depending on the particular dataset. Can be optimized using <a href="#">tune</a> .
<code>lambda</code>	Parameter controlling the amount of L2 penalization for logistic regression, usually taken to be a small value in order to stabilize estimation in the case of separable data.
<code>plot</code>	If <code>comp</code> $\leq$ 2, should the classification space of the Partial Least Squares components be plotted? Default is <code>FALSE</code> .
<code>models</code>	a logical value indicating whether the model object shall be returned

**Value**

An object of class `cloutput`.

**Note**

Up to now, only the two-class case is supported.

---

pls\_rfcMA-methods *Partial Least Squares followed by random forests*

---

**Description**

This method constructs a classifier that extracts Partial Least Squares components used to generate Random Forests, s. [rfCMA](#). The Partial Least Squares components are computed by the package [plsgenomics](#).

**Methods**

**X = "matrix", y = "numeric", f = "missing"** signature 1

**X = "matrix", y = "factor", f = "missing"** signature 2

**X = "data.frame", y = "missing", f = "formula"** signature 3

**X = "ExpressionSet", y = "character", f = "missing"** signature 4

For further argument and output information, consult [pls\\_rfcMA](#).

pls\_rfCMA

*Partial Least Squares followed by random forests***Description**

This method constructs a classifier that extracts Partial Least Squares components used to generate Random Forests, s. [rfCMA](#).

For S4 method information, see [pls\\_rfCMA-methods](#).

**Usage**

```
pls_rfCMA(X, y, f, learnind, comp = 2 * nlevels(as.factor(y)), seed = 111, models
```

**Arguments**

X	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
y	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if X is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if X is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
f	A two-sided formula, if X is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
learnind	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
comp	Number of Partial Least Squares components to extract. Default ist two times the number of different classes.
seed	Fix Random number generator seed to <code>seed</code> . This is useful to guarantee reproducibility of the results, due to the random component in the random Forest.
models	a logical value indicating whether the model object shall be returned
...	Further arguments to be passed to <code>randomForests</code> from the package of the same name.

**Value**

An object of class `cloutput`.

pnnCMA-methods

*Probabilistic Neural Networks*

---

## Description

Probabilistic Neural Networks is the term Specht (1990) used for a Gaussian kernel estimator for the conditional class densities.

## Methods

**X = "matrix", y = "numeric", f = "missing"** signature 1

**X = "matrix", y = "factor", f = "missing"** signature 2

**X = "data.frame", y = "missing", f = "formula"** signature 3

**X = "ExpressionSet", y = "character", f = "missing"** signature 4

For references, further argument and output information, consult [pnnCMA](#).

pnnCMA

*Probabilistic Neural Networks***Description**

Probabilistic Neural Networks is the term Specht (1990) used for a Gaussian kernel estimator for the conditional class densities.

For S4 method information, see [pnnCMA-methods](#).

**Usage**

```
pnnCMA(X, y, f, learnind, sigma = 1, models=FALSE)
```

**Arguments**

X	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A matrix. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>. Each variable (gene) will be scaled for unit variance and zero mean.</li> </ul>
y	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if X is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if X is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
f	A two-sided formula, if X is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
learnind	An index vector specifying the observations that belong to the learning set. For this method, this must <i>not</i> be <code>missing</code> .
sigma	Standard deviation of the Gaussian Kernel used. This hyperparameter should be tuned, s. <a href="#">tune</a> . The default is 1, but this generally does not lead to good results. Actually, this method reacts very sensitively to the value of sigma. Take care if warnings appear related to the particular choice.
models	a logical value indicating whether the model object shall be returned

**Value**

An object of class `cloutput`.

**Note**

There is actually no strong relation of this method to Feed-Forward Neural Networks, s. [nnetCMA](#).

**Author(s)**

**Examples**

```
### load Golub AML/ALL data
data(golub)
### extract class labels
golubY <- golub[,1]
### extract gene expression from first 10 genes
golubX <- as.matrix(golub[,2:11])
### select learningset
ratio <- 2/3
set.seed(111)
learnind <- sample(length(golubY), size=floor(ratio*length(golubY)))
### run PNN
pnnresult <- pnnCMA(X=golubX, y=golubY, learnind=learnind, sigma = 3)
### show results
show(pnnresult)
ftable(pnnresult)
plot(pnnresult)
```

---

prediction-methods *General method for predicting class labels of new observations*

---

**Description**

Perform prediction signatures:

**Methods**

**X.tr = "matrix", X.new="matrix", y.tr='any', f = "missing"** signature 1

**X.tr = "data.frame", X.new="data.frame", y.tr = "missing", f = "formula"** signature 2

**X.tr = "ExpressionSet", X.new = "ExpressionSet", y.tr = "character", f = "missing"** signature 3

For further argument and output information, consult [classification](#).

---

prediction

*General method for predicting classes of new observations*

---

### Description

This method constructs the given classifier using the specified training data, gene selection and tuning results.. Subsequently, class labels are predicted for new observations.

For S4 method information, s. [classification-methods](#).

### Usage

```
prediction(X.tr, y.tr, X.new, f, classifier, genesel, models=F, nbgene, tuner, ...)
```

### Arguments

- |                      |  |
|----------------------|--|
| <code>X.tr</code>    | <p>Training gene expression data. Can be one of the following:</p> <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>   |
| <code>X.new</code>   | <p>gene expression data. Can be one of the following:</p> <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>  |
| <code>y.tr</code>    | <p>Class labels of training observation. Can be one of the following:</p> <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• missing, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded for classifier construction to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p> |
| <code>f</code>       | <p>A two-sided formula, if <code>X</code> is a <code>data.frame</code>. The left part correspond to class labels, the right to variables.</p>  |
| <code>genesel</code> | <p>Optional (but usually recommended) object of class <code>genesel</code> containing variable importance information for the argument <code>learningsets</code>. In this case the object contains a single variable selection. Appropriate <code>genesel</code>-objects can be obtained using the function <code>genesel</code> without <code>learningset</code> and setting <code>X=X.tr</code> and <code>y=y.tr</code> (i.e. corresponding to the training data of this function).</p>  |
| <code>nbgene</code>  | <p>Number of best genes to be kept for classification, based on either <code>genesel</code> or the call to <code>GeneSelection</code> using <code>genesellist</code>. In the case that both are missing, this argument is not necessary. <b>note:</b></p> <ul style="list-style-type: none"> <li>• If the gene selection method has been one of "lasso", "elasticnet", "boosting", <code>nbgene</code> will be reset to <math>\min(s, \text{nbgene})</math> where <code>s</code> is the number of nonzero coefficients.</li> </ul>   |

- if the gene selection scheme has been "one-vs-all", "pairwise" for the multiclass case, there exist several rankings. The top `nbgene` will be kept of *each* of them, so the number of effective used genes will sometimes be much larger.

<code>classifier</code>	Name of function ending with <code>CMA</code> indicating the classifier to be used.
<code>tuneres</code>	Analogous to the argument <code>genesel</code> - object of class <code>tuningresult</code> containing information about the best hyperparameter choice for the argument <code>learningsets</code> . Appropriate tuning-objects can be obtained using the function <code>tune</code> without <code>learningsets</code> and setting parameters <code>X=X.tr</code> , <code>y=y.tr</code> and <code>genesel=genesel</code> (i.e. using the same training data and gene selection as in this function)
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments passed to the function <code>classifier</code> .

### Details

This function builds the specified classifier and predicts the class labels of new observations. Hence, its usage differs from those of most other prediction functions in R.

### Value

A object of class `predoutput-class`; Predicted classes can be seen by `show(predoutput)`

---

 qdaCMA

*Quadratic Discriminant Analysis*

---

## Description

Performs a quadratic discriminant analysis under the assumption of a multivariate normal distribution in each classes without restriction concerning the covariance matrices. The function `qda` from the package `MASS` is called for computation.

For S4 method information, see [qdaCMA-methods](#).

## Usage

```
qdaCMA(X, y, f, learnind, models=FALSE, ...)
```

## Arguments

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A <code>factor</code>.</li> <li>• A <code>character</code> if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments to be passed to <code>qda</code> from the package <code>MASS</code>

## Value

An object of class `cloutput`.

**Note**

Excessive variable selection has usually to be performed before qdaCMA can be applied in the  $p > n$  setting. Not reducing the number of variables can result in an error message.

```

**Description**

Random Forests were proposed by Breiman (2001) and are implemented in the package `randomForest`. In this package, they can as well be used to rank variables according to their importance, s. `GeneSelection`.

**Methods**

**X = "matrix", y = "numeric", f = "missing"** signature 1

**X = "matrix", y = "factor", f = "missing"** signature 2

**X = "data.frame", y = "missing", f = "formula"** signature 3

**X = "ExpressionSet", y = "character", f = "missing"** signature 4

For references, further argument and output information, consult [rfCMA](#)

**Description**

Random Forests were proposed by Breiman (2001) and are implemented in the package `randomForest`. In this package, they can as well be used to rank variables according to their importance, s. `GeneSelection`. For S4 method information, see [rfCMA-methods](#)

**Usage**

```
rfCMA(X, y, f, learnind, varimp = TRUE, seed = 111, models=FALSE, ...)
```

**Arguments**

- |   |  |
|---|--|
| X | Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>   |
| y | Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if X is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if X is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p> |
| f | A two-sided formula, if X is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.   |

learnind	An index vector specifying the observations that belong to the learning set. May be missing; in that case, the learning set consists of all observations and predictions are made on the learning set.
varimp	Should variable importance measures be computed ? Defaults to TRUE.
seed	Fix Random number generator seed to seed. This is useful to guarantee reproducibility of the results.
models	a logical value indicating whether the model object shall be returned
...	Further arguments to be passed to <code>randomForest</code> from the package of the same name.

### Value

If `varimp`, then an object of class `clvarseloutput` is returned, otherwise an object of class `cloutput`

### show results
#show(rfresult)
#ftable(rfresult)
#plot(rfresult)
```

---

`roc`*Receiver Operator Characteristic*

---

**Description**

The empirical Receiver Operator Characteristic (ROC) is widely used for the evaluation of diagnostic tests, but also for the evaluation of classifiers. In this implementation, it can only be used for the binary classification case. The input are a numeric vector of class probabilities (which play the role of a test result) and the true class labels. Note that misclassification performance can (partly widely) differ from the Area under the ROC (AUC). This is due to the fact that misclassification rates are always computed for the threshold 'probability = 0.5'.

**Arguments**

<code>object</code>	An object of <code>cloutput</code> .
<code>plot</code>	Should the ROC curve be plotted ? Default is TRUE.
<code>...</code>	Argument to specify further graphical options.

**Value**

The empirical area under the curve (AUC).

`scdaCMA-methods`*Shrunken Centroids Discriminant Analysis*

---

**Description**

The nearest shrunken centroid classification algorithm is detailly described in Tibshirani et al. (2002).

It is widely known under the name PAM (prediction analysis for microarrays), which can also be found in the package `pamr`.

## Methods

`X = "matrix", y = "numeric", f = "missing"` signature 1

`X = "matrix", y = "factor", f = "missing"` signature 2

`X = "data.frame", y = "missing", f = "formula"` signature 3

`X = "ExpressionSet", y = "character", f = "missing"` signature 4

For references, further argument and output information, consult [scdaCMA](#).

scdaCMA

*Shrunken Centroids Discriminant Analysis*

## Description

The nearest shrunken centroid classification algorithm is detailly described in Tibshirani et al. (2002).

It is widely known under the name PAM (prediction analysis for microarrays), which can also be found in the package `pamr`.

For S4 method information, see [scdaCMA-methods](#).

## Usage

```
scdaCMA(X, y, f, learnind, delta = 0.5, models=FALSE, ...)
```

## Arguments

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A <code>factor</code>.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>delta</code>	The shrinkage intensity for the class centroids - a hyperparameter that must be tuned. The default <code>0.5</code> not necessarily produces good results.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Currently unused argument.

**Value**

An object of class `cloutput`.

**Note**

The results can differ from those obtained by using the package `pamr`.

shrinkldaCMA-methods

*Shrinkage linear discriminant analysis*

---

**Description**

Linear Discriminant Analysis combined with the James-Stein-Shrinkage approach of Schaefer and Strimmer (2005) for the covariance matrix.

Currently still an experimental version. For S4 method information, see [shrinkldaCMA-methods](#)

## Methods

`X = "matrix", y = "numeric", f = "missing"` signature 1  
`X = "matrix", y = "factor", f = "missing"` signature 2  
`X = "data.frame", y = "missing", f = "formula"` signature 3  
`X = "ExpressionSet", y = "character", f = "missing"` signature 4  
 For further argument and output information, consult [shrinkldaCMA](#).

shrinkldaCMA

*Shrinkage linear discriminant analysis*

## Description

Linear Discriminant Analysis combined with the James-Stein-Shrinkage approach of Schaefer and Strimmer (2005) for the covariance matrix.

Currently still an experimental version.

For S4 method information, see [shrinkldaCMA-methods](#)

## Usage

```
shrinkldaCMA(X, y, f, learnind, models=FALSE, ...)
```

## Arguments

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments to be passed to <code>cov.shrink</code> from the package <code>corpcor</code>

## Value

An object of class `cloutput`.

**Note**

This is still an experimental version.

Covariance shrinkage is performed by calling functions from the package `corpcor`.

Variable selection is *not* necessary.

result <- shrinkldaCMA(X=golubX, y=golubY, learnind=learnind)
### show results
show(result)
ftable(result)
plot(result)
```

---

summary

*Summarize classifier evaluation*

---

**Description**

This method principally does nothing more than applying the pre-implemented `summary()` function to the slot `score` of an object of class `evaloutput`. One then obtains the usual five-point-summary, consisting of minimum and maximum, lower and upper quartile and the median. Additionally, the mean is also shown.

**Arguments**

`object`      An object of class `evaloutput`.  
`...`        Further arguments passed to the pre-implemented `summary` function.

**Value**

No return.

**Note**

That the results normally differ for different evaluation schemes ("iterationwise" or "observation-wise").

**Author(s)**

Martin Slawski <ms@cs.uni-sb.de>

Anne-Laure Boulesteix <boulesteix@ibe.med.uni-muenchen.de>

**See Also**

svmCMA-methods

*Support Vector Machine*

---

**Description**

Calls the function `svm` from the package `e1071` that provides an interface to the award-winning LIBSVM routines.

**Methods**

`X = "matrix", y = "numeric", f = "missing"` signature 1

`X = "matrix", y = "factor", f = "missing"` signature 2

`X = "data.frame", y = "missing", f = "formula"` signature 3

`X = "ExpressionSet", y = "character", f = "missing"` signature 4

For further argument and output information, consult [svmCMA](#).

svmCMA

*Support Vector Machine***Description**

Calls the function `svm` from the package `e1071` that provides an interface to the award-winning LIBSVM routines. For S4 method information, see [svmCMA-methods](#)

**Usage**

```
svmCMA(X, y, f, learnind, probability, models=FALSE, seed=341, ...)
```

**Arguments**

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A <code>factor</code>.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul> <p><b>WARNING:</b> The class labels will be re-coded to range from 0 to <math>K-1</math>, where <math>K</math> is the total number of different classes in the learning set.</p>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learnind</code>	An index vector specifying the observations that belong to the learning set. May be <code>missing</code> ; in that case, the learning set consists of all observations and predictions are made on the learning set.
<code>probability</code>	logical indicating whether the model should allow for probability predictions.
<code>seed</code>	Fix random number generator for reproducibility.
<code>models</code>	a logical value indicating whether the model object shall be returned
<code>...</code>	Further arguments to be passed to <code>svm</code> from the package <code>e1071</code>

**Value**

An object of class `cloutput`.

**Note**

Contrary to the default settings in `e1071:::svm`, the used kernel is a linear kernel which has turned to be out a better default setting in the small sample, large number of predictors - situation, because additional nonlinearity is mostly not necessary there. It additionally avoids the tuning of a further kernel parameter `gamma`, s. help of the package `e1071` for details.

Nevertheless, hyperparameter tuning concerning the parameter `cost` must usually be performed to obtain reasonable results, s. [tune](#).

```
### load Golub AML/ALL data
data(golub)
### extract class labels
golubY <- golub[,1]
### extract gene expression
golubX <- as.matrix(golub[,-1])
### select learningset
ratio <- 2/3
set.seed(111)
learnind <- sample(length(golubY), size=floor(ratio*length(golubY)))
### run _untuned_linear SVM
svmresult <- svmCMA(X=golubX, y=golubY, learnind=learnind,probability=TRUE)
### show results
show(svmresult)
ftable(svmresult)
plot(svmresult)
```

---

toplist

*Display 'top' variables*

---

**Description**

This is a convenient method to get quick access to the most important variables, based on the result of call to [GeneSelection](#).

**Usage**

```
toplist(object, k = 10, iter = 1, show = TRUE, ...)
```

**Arguments**

<code>object</code>	An object of <code>genesel</code> .
<code>k</code>	Number of top genes for which information should be displayed. Defaults to 10.
<code>iter</code>	iteration number ( <code>learningset</code> ) for which tuning results should be displayed.
<code>show</code>	Should the results be printed ? Default is <code>TRUE</code> .
<code>...</code>	Currently unused argument.

**Value**

The type of output depends on the gene selection scheme. For the multiclass case, if gene selection has been run with the "pairwise" or "one-vs-all" scheme, then the output will be a list of `data.frames`, each containing the gene indices plus variable importance for the top `k` genes. The list elements are named according to the binary scenarios (e.g., 1 vs. 3). Otherwise, a single `data.frame` is returned.

tune-methods

*Hyperparameter tuning for classifiers*

---

**Description**

Performs hyperparameter tuning for the following signatures:

**Methods**

`X = "matrix", y = "numeric", f = "missing"` signature 1

`X = "matrix", y = "factor", f = "missing"` signature 2

`X = "data.frame", y = "missing", f = "formula"` signature 3

`X = "ExpressionSet", y = "character", f = "missing"` signature 4

For further argument and output information, consult [tune](#).

## Description

Most classifiers implemented in this package depend on one or even several hyperparameters (s. details) that should be optimized to obtain good (and comparable !) results. As tuning scheme, we propose three fold Cross-Validation on each `learningset` (for fixed selected variables). Note that `learningsets` usually do not contain the complete dataset, so tuning involves a second level of splitting the dataset. Increasing the number of folds leads to larger datasets (and possibly to higher accuracy), but also to higher computing times.

For S4 method information, s. `link{tune-methods}`

## Usage

```
tune(X, y, f, learningsets, genesel, genesellist = list(), nbgene, classifier, f
```

## Arguments

<code>X</code>	Gene expression data. Can be one of the following: <ul style="list-style-type: none"> <li>• A <code>matrix</code>. Rows correspond to observations, columns to variables.</li> <li>• A <code>data.frame</code>, when <code>f</code> is <i>not</i> missing (s. below).</li> <li>• An object of class <code>ExpressionSet</code>.</li> </ul>
<code>y</code>	Class labels. Can be one of the following: <ul style="list-style-type: none"> <li>• A numeric vector.</li> <li>• A factor.</li> <li>• A character if <code>X</code> is an <code>ExpressionSet</code> that specifies the phenotype variable.</li> <li>• <code>missing</code>, if <code>X</code> is a <code>data.frame</code> and a proper formula <code>f</code> is provided.</li> </ul>
<code>f</code>	A two-sided formula, if <code>X</code> is a <code>data.frame</code> . The left part correspond to class labels, the right to variables.
<code>learningsets</code>	An object of class <code>learningsets</code> . May be missing, then the complete datasets is used as learning set.
<code>genesel</code>	Optional (but usually recommended) object of class <code>genesel</code> containing variable importance information for the argument <code>learningsets</code>
<code>genesellist</code>	In the case that the argument <code>genesel</code> is missing, this is an argument list passed to <code>GeneSelection</code> . If both <code>genesel</code> and <code>genesellist</code> are missing, no variable selection is performed.
<code>nbgene</code>	Number of best genes to be kept for classification, based on either <code>genesel</code> or the call to <code>GeneSelection</code> using <code>genesellist</code> . In the case that both are missing, this argument is not necessary. <b>note:</b> <ul style="list-style-type: none"> <li>• If the gene selection method has been one of "lasso", "elasticnet", "boosting", <code>nbgene</code> will be reset to <code>min(s, nbgene)</code> where <code>s</code> is the number of nonzero coefficients.</li> <li>• if the gene selection scheme has been "one-vs-all", "pairwise" for the multiclass case, there exist several rankings. The top <code>nbgene</code> will be kept of <i>each</i> of them, so the number of effective used genes will sometimes be much larger.</li> </ul>

<code>classifier</code>	Name of function ending with <code>CMA</code> indicating the classifier to be used.
<code>fold</code>	The number of cross-validation folds used within each <code>learningset</code> . Default is 3. Increasing <code>fold</code> will lead to higher computing times.
<code>strat</code>	Should stratified cross-validation according to the class proportions in the complete dataset be used ? Default is <code>FALSE</code> .
<code>grids</code>	A named list. The names correspond to the arguments to be tuned, e.g. <code>k</code> (the number of nearest neighbours) for <code>knnCMA</code> , or <code>cost</code> for <code>svmCMA</code> . Each element is a numeric vector defining the grid of candidate values. Of course, several hyperparameters can be tuned simultaneously (though requiring much time). By default, <code>grids</code> is an empty list. In that case, a pre-defined list will be used, s. details.
<code>trace</code>	Should progress be traced ? Default is <code>TRUE</code> .
<code>...</code>	Further arguments to be passed to <code>classifier</code> , of course not one of the arguments to be tuned (!).

### Details

The following default settings are used, if the arguments `grids` is an empty list:

```

gbmCMA n.trees = c(50, 100, 200, 500, 1000)
compBoostCMA mstop = c(50, 100, 200, 500, 1000)
LassoCMA norm.fraction = seq(from=0.1, to=0.9, length=9)
ElasticNetCMA norm.fraction = seq(from=0.1, to=0.9, length=5), lambda2
  = 2^{-(5:1)}
plrCMA lambda = 2^{-4:4}
pls_ldaCMA comp = 1:10
pls_lrCMA comp = 1:10
pls_rfcCMA comp = 1:10
rfCMA mtry = ceiling(c(0.1, 0.25, 0.5, 1, 2)*sqrt(ncol(X))), nodesize
  = c(1,2,3)
knnCMA k=1:10
pknnCMA k = 1:10
scdaCMA delta = c(0.1, 0.25, 0.5, 1, 2, 5)
pnnCMA sigma = c(2^{-2:2}),
nnetCMA size = 1:5, decay = c(0, 2^{-(4:1)})
svmCMA, kernel = "linear" cost = c(0.1, 1, 5, 10, 50, 100, 500)
svmCMA, kernel = "radial" cost = c(0.1, 1, 5, 10, 50, 100, 500), gamma
  = 2^{-2:2}
svmCMA, kernel = "polynomial" cost = c(0.1, 1, 5, 10, 50, 100, 500),
  degree = 2:4

```

### Value

An object of class `tuningresult`

**Note**

The computation time can be enormously high. Note that for each different learningset, the classifier must be trained `foldtimes` number of possible different hyperparameter combinations times. E.g. if the number of the learningsets is fifty, `fold = 3` and two hyperparameters (each with 5 candidate values) are tuned,  $50 \times 3 \times 25 = 3750$  training iterations are necessary !

## End(Not run)
```

---

tuningresult-class "*tuningresult*"

---

**Description**

Object returned by the function [tune](#)

**Slots**

**hypergrid:** A `data.frame` representing the grid of values that were tried and evaluated. The number of columns equals the number of tuned hyperparameters and the number rows equals the number of all possible combinations of the discrete grids.

**tuneres:** A list whose lengths equals the number of different `learningsets` for which tuning has been performed and whose elements are numeric vectors with length equal to the number of rows of `hypergrid` (s.above), containing the misclassification rate belonging to the respective hyperparameter/hyperparameter combination. In order to get an overview about the best hyperparameter/hyperparameter combination, use the convenience method `best`

**method:** Name of the classifier that has been tuned.

**fold:** Number of cross-validation fold used for tuning, s. argument of the same name in `tune`

**Methods**

**show** Use `show(tuninresult-object)` for brief information.

**best** Use `best(tuningresult-object)` to see which hyperparameter/hyperparameter combination has performed best in terms of the misclassification rate, s. `best,tuningresult-method`

**plot** Use `plot(tuningresult-object, iter, which)` to display the performance of hyperparameter/hyperparameter combinations graphically, either as one-dimensional or as two-dimensional (contour) plot, s. `plot,tuningresult-method`

**Author(s)**

Martin Slawski <ms@cs.uni-sb.de>

Anne-Laure Boulesteix <boulesteix@ibe.med.uni-muenchen.de>

**See Also**

`tune`

---

`varseloutput-class "varseloutput"`

---

**Description**

An object returned by the functions described in `filter`, usually not created directly by the user.

**Slots**

**varsel:** numeric vector of variable importance measures, e.g. absolute of genewise statistics.

**Methods**

No methods are currently defined.

**Author(s)**

Martin Slawski <ms@cs.uni-sb.de>

Anne-Laure Boulesteix <boulesteix@ibe.med.uni-muenchen.de>
