### 1 Introduction

The *GenomicRanges* package serves as the foundation for representing genomic locations within the *Bioconductor* project. In the *Bioconductor* package hierarchy, it builds upon the *IRanges* (infrastructure) package and provides support for the *BSgenome* (infrastructure), *Rsamtools* (I/O), *ShortRead* (I/O & QA), *rtracklayer* (I/O), *GenomicFeatures* (infrastructure), *GenomicAlignments* (sequence reads), *VariantAnnotation* (called variants), and many other *Bioconductor* packages.

This package lays a foundation for genomic analysis by introducing three classes (*GRanges*, *GPos*, and *GRangesList*), which are used to represent genomic ranges, genomic positions, and groups of genomic ranges. This vignette focuses on the *GRanges* and *GRangesList* classes and their associated methods.

The *GenomicRanges* package is available at https://bioconductor.org and can be installed via biocLite:

> source("https://bioconductor.org/biocLite.R")

> biocLite("GenomicRanges")

A package only needs to be installed once. Load the package into an R session with

> library(GenomicRanges)

### 2 *GRanges*: Genomic Ranges

The *GRanges* class represents a collection of genomic ranges that each have a single start and end location on the genome. It can be used to store the location of genomic features such as contiguous binding sites, transcripts, and exons. These objects can be created by using the <u>GRanges</u> constructor function. For example,

```
> gr <- GRanges(</pre>
      seqnames = Rle(c("chr1", "chr2", "chr1", "chr3"), c(1, 3, 2, 4)),
+
      ranges = IRanges(101:110, end = 111:120, names = head(letters, 10)),
+
     strand = Rle(strand(c("-", "+", "*", "+", "-")), c(1, 2, 2, 3, 2)),
+
      score = 1:10,
     GC = seq(1, 0, length=10))
+
> gr
GRanges object with 10 ranges and 2 metadata columns:
    seqnames
                ranges strand |
                                   score
                                                         GC
       <Rle> <IRanges> <Rle> | <integer>
                                                  <numeric>

        chr3
              109-119
                           - |
                                       9 0.111111111111111
             110-120
  i
        chr3
                          - |
                                       10
                                                          0
  seqinfo: 3 sequences from an unspecified genome; no seqlengths
```

> options(warn=2)

creates a *GRanges* object with 10 genomic ranges. The output of the *GRanges* show method separates the information into a left and right hand region that are separated by | symbols. The genomic coordinates (seqnames, ranges, and strand) are located on the left-hand side and the metadata columns (annotation) are located on the right. For this example, the metadata is comprised of score and GC information, but almost anything can be stored in the metadata portion of a *GRanges* object.

The components of the genomic coordinates within a *GRanges* object can be extracted using the seqnames, ranges, and strand accessor functions.

```
> seqnames(gr)
```

```
factor-Rle of length 10 with 4 runs
                3
                       2

                              11
> strand(gr)
factor-Rle of length 10 with 5 runs
  Lengths: 1 2 2 3 2
  Values : - + * + -
Levels(3): + - *
```

The genomic ranges can be extracted without corresponding metadata with granges

```
> granges(gr)
```

```
GRanges object with 10 ranges and 0 metadata columns:
   seqnames
              ranges strand
      <Rle> <IRanges> <Rle>
 а
      chr1 101-111 -
     chr2 102-112
 b
                        +
       chr2 103-113
 С
                         +
  .
       ...
                 ... ...
       chr3 108-118 +
 h
       chr3 109-119
 i
       chr3 110-120
 j
                         -
 - - - - -
      - -
 seqinfo: 3 sequences from an unspecified genome; no seqlengths
```

Annotations for these coordinates can be extracted as a *DataFrame* object using the mcols accessor.

> mcols(gr) DataFrame with 10 rows and 2 columns score GC <integer> <numeric> 1 1 1 2 2 0.88888888888888888 3 3 0.777777777777778 . . . . . . . . .

Information about the lengths of the various sequences that the ranges are aligned to can also be stored in the *GRanges* object. So if this is data from *Homo sapiens*, we can set the values as:

```
> seqlengths(gr) <- c(249250621, 243199373, 198022430)
```

And then retrieves as:

Methods for accessing the length and names have also been defined.

```
> names(gr)
[1] "a" "b" "c" "d" "e" "f" "g" "h" "i" "j"
> length(gr)
[1] 10
```

#### 2.1 Splitting and combining *GRanges* objects

*GRanges* objects can be devided into groups using the split method. This produces a *GRangesList* object, a class that will be discussed in detail in the next section.

```
> sp <- split(gr, rep(1:2, each=5))</pre>
> sp
GRangesList object of length 2:
$1
GRanges object with 5 ranges and 2 metadata columns:
              ranges strand |
                                                     GC
   segnames
                                 score
      <Rle> <IRanges> <Rle> | <integer>
                                              <numeric>
       chrl 101-111
                        - |
                                  1
                                                      1
 а
       chr2 102-112
                         + |
                                    2 0.888888888888888888
 b
                                   3 0.7777777777777778

 j
 seqinfo: 3 sequences from an unspecified genome
```

#### 2.2 Subsetting *GRanges* objects

*GRanges* objects act like vectors of ranges, with the expected vector-like subsetting operations available

> gr[2:3]

A second argument to the [ subset operator can be used to specify which metadata columns to extract from the *GRanges* object. For example,

Elements can also be assigned to the *GRanges* object. Here is an example where the second row of a *GRanges* object is replaced with the first row of gr.

```
> singles <- split(gr, names(gr))</pre>
> grMod <- gr
> grMod[2] <- singles[[1]]</pre>
> head(grMod, n=3)
GRanges object with 3 ranges and 2 metadata columns:
              ranges strand | score
   segnames
                                                   GC
      <Rle> <IRanges> <Rle> | <integer>
                                             <numeric>
      chr1 101-111 - | 1
                                                    1
 а
       chrl 101-111
                        -
                                   1
 b
                                                    1
                        + | 3 0.77777777777778
       chr2 103-113
 С
 seqinfo: 3 sequences from an unspecified genome
```

There are methods to repeat, reverse, or select specific portions of GRanges objects.

```
> rep(singles[[2]], times = 3)
```

```

#### 2.3 Basic interval operations for *GRanges* objects

Basic interval characteristics of GRanges objects can be extracted using the start, end, width, and range methods.

```
> g <- gr[1:3]
> g <- append(g, singles[[10]])
> start(g)
[1] 101 102 103 110
> end(g)
[1] 111 112 113 120
> width(g)
[1] 11 11 11 11
```

The *GRanges* class also has many methods for manipulating the ranges. The methods can be classified as *intra-range methods*, *inter-range methods*, and *between-range methods*.

*Intra-range methods* operate on each element of a *GRanges* object independent of the other ranges in the object. For example, the flank method can be used to recover regions flanking the set of ranges represented by the *GRanges* object. So to get a *GRanges* object containing the ranges that include the 10 bases upstream of the ranges:

```
> flank(g, 10)
```

GRanges object with 4 ranges and 2 metadata columns:								
	seqnames	ranges	strand	score	GC			
	<rle></rle>	<iranges></iranges>	<rle></rle>	<integer></integer>	<numeric></numeric>			
а	chr1	112-121	-	1	1			
b	chr2	92-101	+	2	0.8888888888888889			
С	chr2	93-102	+	3	0.777777777777778			
j	chr3	121-130	-	10	Θ			
seqinfo: 3 sequences from an unspecified genome								

And to include the downstream bases:

```
> flank(g, 10, start=FALSE)
GRanges object with 4 ranges and 2 metadata columns:
   seqnames
            ranges strand | score
                                                  GC
      <Rle> <IRanges> <Rle> | <integer>
                                           <numeric>
 а
       chr1 91-100 - | 1
                                                  1
 b
       chr2 113-122
                       + |
                                  2 0.88888888888888888
       chr2 114-123
                        + |
                                  3 0.777777777777778
 с
       chr3 100-109
                                  10
                                                   0
 j
                       - |
 seqinfo: 3 sequences from an unspecified genome
```

Other examples of intra-range methods include resize and shift. The shift method will move the ranges by a specific number of base pairs, and the resize method will extend the ranges by a specified width.

```
> shift(g, 5)
GRanges object with 4 ranges and 2 metadata columns:
    seqnames ranges strand | score GC
    <Rle> <IRanges> <Rle> | <integer> <numeric>
```

```

 а
       chr2 102-131
                                     2 0.88888888888888888
 b
                          + |
       chr2 103-132
                                     3 0.7777777777777778
 с
                          + |
       chr3
              91-120
                                     10
                                                       0
 i
                         - |
  seqinfo: 3 sequences from an unspecified genome
```

The *GenomicRanges* help page ?"intra-range-methods" summarizes these methods.

*Inter-range methods* involve comparisons between ranges in a single *GRanges* object. For instance, the reduce method will align the ranges and merge overlapping ranges to produce a simplified set.

```
> reduce(g)
```

```
GRanges object with 3 ranges and 0 metadata columns:
    seqnames ranges strand
    <Rle> <IRanges> <Rle>
[1] chr1 101-111 -
[2] chr2 102-113 +
[3] chr3 110-120 -
--------
seqinfo: 3 sequences from an unspecified genome
```

Sometimes one is interested in the gaps or the qualities of the gaps between the ranges represented by your *GRanges* object. The gaps method provides this information: reduced version of your ranges:

```
> gaps(g)
```

GRanges object with 12 ranges and 0 metadata columns: segnames ranges strand <Rle> <IRanges> <Rle> [1] chr1 1-249250621 + [2] chr1 1-100 [3] chr1 112-249250621 . . . . . . . . . . . . [10] chr3 1-109 [11] chr3 121-198022430 [12] chr3 1-198022430 \* seqinfo: 3 sequences from an unspecified genome

The disjoin method represents a *GRanges* object as a collection of non-overlapping ranges:

```
> disjoin(g)
GRanges object with 5 ranges and 0 metadata columns:
      segnames
                  ranges strand
         <Rle> <IRanges> <Rle>
  [1]
          chr1
                 101-111
  [2]
          chr2
                     102
                               +
  [3]
          chr2 103-112
                               +
  [4]
          chr2
                     113
                               +
          chr3 110-120
  [5]
  - - - - - - -
  seqinfo: 3 sequences from an unspecified genome
```

The coverage method quantifies the degree of overlap for all the ranges in a *GRanges* object.

```
> coverage(g)
RleList of length 3
$chr1
integer-Rle of length 249250621 with 3 runs

  Values :
                  0
                            1
                                      0
```

See the GenomicRanges help page ?"inter-range-methods" for additional help.

*Between-range methods* involve operations between two *GRanges* objects; some of these are summarized in the next section.

#### 2.4 Interval set operations for *GRanges* objects

Between-range methods calculate relationships between different *GRanges* objects. Of central importance are find0verlaps and related operations; these are discussed below. Additional operations treat *GRanges* as mathematical sets of coordinates; union(g, g2) is the union of the coordinates in g and g2. Here are examples for calculating the union, the intersect and the asymmetric difference (using setdiff).

```
> g2 <- head(gr, n=2)
> union(g, g2)
GRanges object with 3 ranges and 0 metadata columns:
    seqnames ranges strand
```

```
<Rle> <IRanges> <Rle>
          chr1
                 101-111
  [1]
  [2]
          chr2
                 102-113
                               +
  [3]
          chr3 110-120
                               -
  - - - - - - -
  seqinfo: 3 sequences from an unspecified genome
> intersect(g, g2)
GRanges object with 2 ranges and 0 metadata columns:
      segnames
                  ranges strand
         <Rle> <IRanges> <Rle>
  [1]
          chrl 101-111
          chr2 102-112
  [2]
                               +
  seqinfo: 3 sequences from an unspecified genome
> setdiff(g, g2)
GRanges object with 2 ranges and 0 metadata columns:
                  ranges strand
      segnames
         <Rle> <IRanges> <Rle>
  [1]
          chr2
                     113
                               +
  [2]
          chr3 110-120
  - - - - - - - -
  seqinfo: 3 sequences from an unspecified genome
```

Related methods are available when the structure of the *GRanges* objects are 'parallel' to one another, i.e., element 1 of object 1 is related to element 1 of object 2, and so on. These operations all begin with a p, which is short for parallel. The methods then perform elementwise, e.g., the union of element 1 of object 1 with element 1 of object 2, etc. A requirement for these operations is that the number of elements in each *GRanges* object is the same, and that both of the objects have the same seqnames and strand assignments throughout.

```
> q3 <- q[1:2]
> ranges(g3[1]) <- IRanges(start=105, end=112)</pre>
> punion(g2, g3)
GRanges object with 2 ranges and 0 metadata columns:

```

For more information on the GRanges classes be sure to consult the manual page.

```
> ?GRanges
```

A relatively comprehensive list of available methods is discovered with

```
> methods(class="GRanges")
```

### 3 GRangesList: Groups of Genomic Ranges

Some important genomic features, such as spliced transcripts that are are comprised of exons, are inherently compound structures. Such a feature makes much more sense when expressed as a compound object such as a *GRangesList*. Whenever genomic features consist of multiple ranges that are grouped by a parent feature, they can be represented as a *GRangesList* object. Consider the simple example of the two transcript <u>GRangesList</u> below created using the <u>GRangesList</u> constructor.

```
> gr1 <- GRanges(</pre>
+
      seqnames = "chr2",
      ranges = IRanges(103, 106),
+
      strand = "+",
+
      score = 5L, GC = 0.45)
+
> gr2 <- GRanges(</pre>
      seqnames = c("chr1", "chr1"),
+
+
      ranges = IRanges(c(107, 113), width = 3),
      strand = c("+", "-"),
+
      score = 3:4, GC = c(0.3, 0.5))
+
> grl <- GRangesList("txA" = gr1, "txB" = gr2)</pre>
> grl
GRangesList object of length 2:
$txA
GRanges object with 1 range and 2 metadata columns:
      segnames
                   ranges strand |
                                        score
                                                      GC
         <Rle> <IRanges> <Rle> | <integer> <numeric>
          chr2 103-106
  [1]
                               + |
                                            5
                                                    0.45
$txB
GRanges object with 2 ranges and 2 metadata columns:
      seqnames ranges strand | score GC
```

[1] chr1 107-109 + | 3 0.3 [2] chr1 113-115 - | 4 0.5 ..... seqinfo: 2 sequences from an unspecified genome; no seqlengths

The show method for a *GRangesList* object displays it as a named list of *GRanges* objects, where the names of this list are considered to be the names of the grouping feature. In the example above, the groups of individual exon ranges are represented as separate *GRanges* objects which are further organized into a list structure where each element name is a transcript name. Many other combinations of grouped and labeled *GRanges* objects are possible of course, but this example is expected to be a common arrangement.

#### 3.1 Basic GRangesList accessors

Just as with *GRanges* object, the components of the genomic coordinates within a *GRanges*-*List* object can be extracted using simple accessor methods. Not surprisingly, the *GRangesList* objects have many of the same accessors as *GRanges* objects. The difference is that many of these methods return a list since the input is now essentially a list of *GRanges* objects. Here are a few examples:

```
> seqnames(grl)
RleList of length 2
$txA
factor-Rle of length 1 with 1 run
  Lengths:
              1
  Values : chr2
Levels(2): chr2 chr1
$txB
factor-Rle of length 2 with 1 run
  Lenaths:
              2
  Values : chr1
Levels(2): chr2 chr1
> ranges(grl)
IRangesList of length 2
$txA
IRanges object with 1 range and 0 metadata columns:
          start
                       end
                               width
      <integer> <integer> <integer>
  [1]
            103
                      106
                                   4
$txB
IRanges object with 2 ranges and 0 metadata columns:
                               width
          start
                      end
      <integer> <integer> <integer>
  [1]
            107
                      109
                                   3
  [2]
            113
                       115
                                   3
```

```
> strand(grl)
RleList of length 2
$txA
factor-Rle of length 1 with 1 run
Lengths: 1
Values : +
Levels(3): + - *
$txB
factor-Rle of length 2 with 2 runs
Lengths: 1 1
Values : + -
Levels(3): + - *
```

The length and names methods will return the length or names of the list and the seqlengths method will return the set of sequence lengths.

```
> length(grl)
[1] 2
> names(grl)
[1] "txA" "txB"
> seqlengths(grl)
chr2 chr1
NA NA
```

The elementNROWS method returns a list of integers corresponding to the result of calling NROW on each individual *GRanges* object contained by the *GRangesList*. This is a faster alternative to calling lapply on the *GRangesList*.

```
> elementNROWS(grl)
txA txB
1 2
```

isEmpty tests if a *GRangesList* object contains anything.

```
> isEmpty(grl)
```

[1] FALSE

In the context of a *GRangesList* object, the mcols method performs a similar operation to what it does on a *GRanges* object. However, this metadata now refers to information at the list level instead of the level of the individual *GRanges* objects.

```
> mcols(grl) <- c("Transcript A","Transcript B")
> mcols(grl)
DataFrame with 2 rows and 1 column
        value
        ccharacter>
1 Transcript A
```

#### 2 Transcript B

 ${\sf Element}{-}{\sf level}$  metadata can be retrieved by unlisting the  ${\sf GRangesList},$  and extracting the metadata

#### 3.2 Combining GRangesList objects

*GRangesList* objects can be unlisted to combine the separate *GRanges* objects that they contain as an expanded *GRanges*.

```
> ul <- unlist(grl)</pre>
> ul
GRanges object with 3 ranges and 2 metadata columns:
      segnames
                   ranges strand |
                                       score
                                                     GC
         <Rle> <IRanges> <Rle> | <integer> <numeric>
  txA
          chr2 103-106
                               + |
                                            5
                                                   0.45
          chr1
                                            3
                                                    0.3
  txΒ
                 107-109
                               + |
          chr1 113-115
                               - |
                                            4
                                                    0.5
  txB
  - - - - - - -
  seqinfo: 2 sequences from an unspecified genome; no seqlengths
```

Append lists using append or c.

A support site user had two *GRangesList* objects with 'parallel' elements, and wanted to combined these element-wise into a single *GRangesList*. One solution is to use pc() – parallel (element-wise) c(). A more general solution is to concatenate the lists and then re-group by some factor, in this case the names of the elements.

```
> grl1 <- GRangesList(</pre>
      gr1 = GRanges("chr2", IRanges(3, 6)),
+
      gr2 = GRanges("chr1", IRanges(c(7,13), width = 3)))
+
> grl2 <- GRangesList(</pre>
      gr1 = GRanges("chr2", IRanges(9, 12)),
+
      gr2 = GRanges("chr1", IRanges(c(25,38), width = 3)))
> pc(grl1, grl2)
GRangesList object of length 2:
$gr1
GRanges object with 2 ranges and 0 metadata columns:
      segnames
                   ranges strand
         <Rle> <IRanges> <Rle>
  [1]
          chr2
                      3-6
```

[2] chr2 9-12 \* \$gr2 GRanges object with 4 ranges and 0 metadata columns: seqnames ranges strand [1] chr1 7-9 [2] chr1 13-15 \* chr1 25-27 [3] chr1 38-40 [4] \* - - - - - - - seqinfo: 2 sequences from an unspecified genome; no seqlengths > grl3 <- c(grl1, grl2) > regroup(grl3, names(grl3)) GRangesList object of length 2: \$gr1 GRanges object with 2 ranges and 0 metadata columns: seqnames ranges strand <Rle> <IRanges> <Rle> [1] chr2 3-6 \* 9-12 [2] chr2 \* \$gr2 GRanges object with 4 ranges and 0 metadata columns: seqnames ranges strand chr1 7-9 [1] \* [2] chr1 13-15 \* chr1 25-27 [3] \* chr1 38-40 [4] \* - - - - - - - seqinfo: 2 sequences from an unspecified genome; no seqlengths

### 3.3 Basic interval operations for *GRangesList* objects

For interval operations, many of the same methods exist for *GRangesList* objects that exist for *GRanges* objects.

```
> start(grl)
IntegerList of length 2
[["txA"]] 103
[["txB"]] 107 113
> end(grl)
IntegerList of length 2
[["txA"]] 106
[["txB"]] 109 115
```

```
> width(grl)
```

IntegerList of length 2
[["txA"]] 4
[["txB"]] 3 3

These operations return a data structure representing, e.g., *IntegerList*, a list where all elements are integers; it can be convenient to use mathematical and other operations on *\*List* objects that work on each element, e.g.,

```
> sum(width(grl)) # sum of widths of each grl element
txA txB
4 6
```

Most of the intra-, inter- and between-range methods operate on *GRangesList* objects, e.g., to shift all the *GRanges* objects in a *GRangesList* object, or calculate the coverage. Both of these operations are also carried out across each *GRanges* list member.

```
> shift(grl, 20)
GRangesList object of length 2:
$txA
GRanges object with 1 range and 2 metadata columns:
     segnames
                 ranges strand |
                                   score
                                             GC
        <Rle> <IRanges> <Rle> | <integer> <numeric>
  [1]
         chr2 123-126
                           + |
                                       5
                                              0.45
$txB
GRanges object with 2 ranges and 2 metadata columns:
     seqnames ranges strand | score GC
  [1]
         chr1 127-129
                                3 0.3
                       + |
         chr1 133-135
  [2]
                          - |
                                4 0.5
seqinfo: 2 sequences from an unspecified genome; no seqlengths
> coverage(grl)
RleList of length 2
$chr2
integer-Rle of length 106 with 2 runs
  Lengths: 102
               4
  Values : 0 1
$chr1
integer-Rle of length 115 with 4 runs
  Lengths: 106 3 3 3
  Values : 0 1 0
                      1
```

#### 3.4 Subsetting *GRangesList* objects

A *GRangesList* object is behaves like a list: [ returns a *GRangesList* containing a subset of the original object; [[ or \$ returns the *GRanges* object at that location in the list.

> grl[1] > grl[[1]] > grl["txA"] > grl\$txB

In addition, subsetting a *GRangesList* also accepts a second parameter to specify which of the metadata columns you wish to select.

```
> grl[1, "score"]
GRangesList object of length 1:
$txA
GRanges object with 1 range and 1 metadata column:
      segnames
                  ranges strand |
                                      score
        <Rle> <IRanges> <Rle> | <integer>
         chr2 103-106
  [1]
                              + |
                                          5
- - - - - - -
seqinfo: 2 sequences from an unspecified genome; no seqlengths
> grl["txB", "GC"]
GRangesList object of length 1:
$txB
GRanges object with 2 ranges and 1 metadata column:
      segnames
                  ranges strand |
                                         GC
         <Rle> <IRanges> <Rle> | <numeric>
          chr1 107-109
  [1]
                            + |
                                        0.3
  [2]
         chr1 113-115
                              - |
                                        0.5
seqinfo: 2 sequences from an unspecified genome; no seqlengths
```

The head, tail, rep, rev, and window methods all behave as you would expect them to for a list object. For example, the elements referred to by window are now list elements instead of *GRanges* elements.

```
> rep(grl[[1]], times = 3)
GRanges object with 3 ranges and 2 metadata columns:
                  ranges strand |
      segnames
                                       score
                                                    GC
         <Rle> <IRanges> <Rle> | <integer> <numeric>
  [1]
          chr2 103-106
                               + |
                                           5
                                                  0.45
  [2]
                                           5
                                                  0.45
          chr2
                 103-106
                               + |
  [3]
          chr2
                 103-106
                               + |
                                           5
                                                  0.45
  . . . . . . .
  seqinfo: 2 sequences from an unspecified genome; no seqlengths
```

```
GRangesList object of length 2:
$txB
GRanges object with 2 ranges and 2 metadata columns:
      segnames
                 ranges strand | score
                                                GC
        <Rle> <IRanges> <Rle> | <integer> <numeric>
  [1]
          chr1 107-109
                           + |
                                 3
                                                0.3
  [2]
         chr1 113-115
                             - |
                                        4

seqinfo: 2 sequences from an unspecified genome; no seqlengths
```

### 3.5 Looping over GRangesList objects

For *GRangesList* objects there is also a family of apply methods. These include lapply, sapply, mapply, endoapply, mendoapply, Map, and Reduce.

The different looping methods defined for *GRangesList* objects are useful for returning different kinds of results. The standard lapply and sapply behave according to convention, with the lapply method returning a list and sapply returning a more simplified output.

```
> lapply(grl, length)
$txA
[1] 1
$txB
[1] 2
> sapply(grl, length)
txA txB
1 2
```

As with *IRanges* objects, there is also a multivariate version of sapply, called mapply, defined for *GRangesList* objects. And, if you don't want the results simplified, you can call the Map method, which does the same things as mapply but without simplifying the output.

```
> grl2 <- shift(grl, 10)
> names(grl2) <- c("shiftTxA", "shiftTxB")</pre>
> mapply(c, grl, grl2)
$txA
GRanges object with 2 ranges and 2 metadata columns:
                   ranges strand |
                                       score
                                                     GC
      segnames
         <Rle> <IRanges> <Rle> | <integer> <numeric>
  [1]
          chr2 103-106
                               + |
                                           5
                                                   0.45
          chr2 113-116
                                           5
                                                   0.45
  [2]
                               + |
  - - - - - - -
  seqinfo: 2 sequences from an unspecified genome; no seqlengths
$txB
GRanges object with 4 ranges and 2 metadata columns:
```

GC segnames ranges strand | score <Rle> <IRanges> <Rle> | <integer> <numeric> + | [1] chr1 107-109 3 0.3 [2] chr1 113-115 - | 4 0.5 [3] chr1 117-119 3 0.3 + | [4] chr1 123-125 - | 4 0.5 - - seqinfo: 2 sequences from an unspecified genome; no seqlengths > Map(c, grl, grl2) \$txA GRanges object with 2 ranges and 2 metadata columns: ranges strand | score seqnames GC <Rle> <IRanges> <Rle> | <integer> <numeric> chr2 103-106 + | 5 0.45 [1] chr2 113-116 + | 5 0.45 [2] . . . . . . . seqinfo: 2 sequences from an unspecified genome; no seqlengths \$txB GRanges object with 4 ranges and 2 metadata columns: seqnames ranges strand | score GC <Rle> <IRanges> <Rle> | <integer> <numeric> [1] chr1 107-109 + | 3 0.3 chr1 0.5 [2] 113-115 - | 4 [3] chr1 117-119 + | 3 0.3 0.5 [4] chr1 123-125 - | 4 seqinfo: 2 sequences from an unspecified genome; no seqlengths

Sometimes you will want to get back a modified version of the *GRangesList* that you originally passed in.

An endomorphism is a transformation of an object to another instance of the same class . This is achieved using the endoapply method, which will return the results as a *GRangesList* object.

```
> endoapply(grl, rev)
GRangesList object of length 2:
$txA
GRanges object with 1 range and 2 metadata columns:

  seqinfo: 2 sequences from an unspecified genome; no seqlengths
```

Explicit element-wise operations (lapply() and friends) on *GRangesList* objects with many elements can be slow. It is therefore beneficial to explore operations that work on \*List objects directly (e.g., many of the 'group generic' operators, see ?S4groupGeneric, and the set and parallel set operators (e.g., union, punion). A useful and fast strategy is to unlist the *GRangesList* to a *GRanges* object, operate on the *GRanges* object, then relist the result, e.g.,

```
> gr <- unlist(grl)
> gr$log_score <- log(gr$score)
> grl <- relist(gr, grl)
> grl
GRangesList object of length 2:
$txA
GRanges object with 1 range and 3 metadata columns:
    seqnames ranges strand | score GC log_score
```

```
<Rle> <IRanges> <Rle> | <integer> <numeric>

```

For more information on the  ${\tt GRangesList}$  classes be sure to consult the manual page and available methods

```
> ?GRangesList
> methods(class="GRangesList")  # _partial_ list
```

## 4 Interval overlaps involving GRanges and GRanges-List objects

Interval overlapping is the process of comparing the ranges in two objects to determine if and when they overlap. As such, it is perhaps the most common operation performed on *GRanges* and *GRangesList* objects. To this end, the *GenomicRanges* package provides a family of interval overlap functions. The most general of these functions is find0verlaps, which takes a query and a subject as inputs and returns a *Hits* object containing the index pairings for the overlapping elements.

```
> mtch <- findOverlaps(gr, grl)
> as.matrix(mtch)
        queryHits subjectHits
[1,] 1 1
[2,] 2 2
[3,] 3 2
```

As suggested in the sections discussing the nature of the *GRanges* and *GRangesList* classes, the index in the above matrix of hits for a *GRanges* object is a single range while for a *GRangesList* object it is the set of ranges that define a "feature".

Another function in the overlaps family is **countOverlaps**, which tabulates the number of overlaps for each element in the query.

> countOverlaps(gr, grl)
txA txB txB
1 1 1

A third function in this family is subsetByOverlaps, which extracts the elements in the query that overlap at least one element in the subject.

```
> subsetByOverlaps(gr,grl)
```

GRanges object with 3 ranges and 3 metadata columns: segnames ranges strand | score GC log\_score <Rle> <IRanges> <Rle> | <integer> <numeric> <numeric> chr2 103-106 5 0.45 1.6094379124341 txA + | chr1 107-109 3 0.3 1.09861228866811 txB + | chr1 113-115 txΒ 4 0.5 1.38629436111989 - | - - - - seqinfo: 2 sequences from an unspecified genome; no seqlengths

Finally, you can use the select argument to get the index of the first overlapping element in the subject for each element in the query.

```
> find0verlaps(gr, grl, select="first")
[1] 1 2 2
> find0verlaps(grl, gr, select="first")
[1] 1 2
```

### 5 Session Information
