1 Reading/displaying/writing images

The package **EBImage** is loaded by the following command.

```
> library("EBImage")
```

The function **readImage** is able to read images from files or URLs. Current supported image formats are JPEG, PNG and TIFF.

```
> f = system.file("images", "lena.png", package="EBImage")  
> lena = readImage(f)
```

Images can be displayed using the function **display**. Pixel intensities should range from 0 (black) to 1 (white).

```
> display(lena)
```

Color images or images with multiple frames can also be read with **readImage**.

Figure 1: lena, lenac

```
> lenac = readImage(system.file("images", "lena-color.png", package="EBImage"))
> display(lenac)
> nuc = readImage(system.file('images', 'nuclei.tif', package='EBImage'))

image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no

> display(nuc)
```

Figure 2: nuc

Images can be written with `writeImage`. The file format is deduced from the file name extension. This is useful to convert image formats, here from PNG format to JPEG format.

```
> writeImage(lena, 'lena.jpeg', quality=85)
> writeImage(lenac, 'lenac.jpeg', quality=85)
```

2 Image objects and matrices

The package `EBImage` uses the class `Image` to store and process images. Images are stored as multi-dimensional arrays containing the pixel intensities. All `EBImage` functions are also able to work with matrices and arrays.

```
> print(lena)
```

```
Image
```

```
  colormode: Grayscale  
 storage.mode: double  
    dim: 512 512  
nb.total.frames: 1  
nb.render.frames: 1
```

```
imageData(object)[1:5,1:6]:
```

	[,1]	[,2]	[,3]	[,4]	[,5]	[,6]
[1,]	0.5372549	0.5372549	0.5372549	0.5372549	0.5372549	0.5490196
[2,]	0.5372549	0.5372549	0.5372549	0.5372549	0.5372549	0.5490196
[3,]	0.5372549	0.5372549	0.5372549	0.5372549	0.5372549	0.5137255
[4,]	0.5333333	0.5333333	0.5333333	0.5333333	0.5333333	0.5098039
[5,]	0.5411765	0.5411765	0.5411765	0.5411765	0.5411765	0.5333333

As matrices, images can be manipulated with all R mathematical operators. This includes `+` to control the brightness of an image, `*` to control the contrast of an image or `^` to control the gamma correction parameter.

```
> lena1 = lena+0.5  
> lena2 = 3*lena  
> lena3 = (0.2+lena)^3
```

Figure 3: `lena`, `lena1`, `lena2`, `lena3`

Others operators include `[]` to crop images, `<` to threshold images or `t` to transpose images.

```
> lena4 = lena[299:376, 224:301]  
> lena5 = lena>0.5  
> lena6 = t(lena)  
> print(median(lena))
```

```
[1] 0.3803922
```

Images with multiple frames are created using `combine` which merges images.

```
> lenacomb = combine(lena, lena*2, lena*3, lena*4)  
> display(lenacomb)
```

Figure 4: `lena`, `lena4`, `lena5`, `lena6`

Figure 5: `lenacomb`

3 Spatial transformations

Specific spatial image transformations are done with the functions `resize`, `rotate`, `translate` and the functions `flip` and `flop` to reflect images.

```
> lena7 = rotate(lena, 30)
> lena8 = translate(lena, c(40, 70))
> lena9 = flip(lena)
```

Figure 6: `lena`, `lena7`, `lena8`, `lena9`

4 Color management

The class `Image` extends the base class `array` and uses the `colormode` slot to store how the color information of the multi-dimensional data should be handled.

As an example, the color image `lenac` is a 512x512x3 array, with a `colormode` slot equals to `Color`. The object is understood as a color image by `EImage` functions.

```
> print(lenac)
```

```
Image
  colormode: Color
  storage.mode: double
  dim: 512 512 3
  nb.total.frames: 3
  nb.render.frames: 1
```

```
imageData(object)[1:5,1:6,1]:
      [,1]      [,2]      [,3]      [,4]      [,5]      [,6]
[1,] 0.8862745 0.8862745 0.8862745 0.8862745 0.8862745 0.8901961
[2,] 0.8862745 0.8862745 0.8862745 0.8862745 0.8862745 0.8901961
[3,] 0.8745098 0.8745098 0.8745098 0.8745098 0.8745098 0.8901961
[4,] 0.8745098 0.8745098 0.8745098 0.8745098 0.8745098 0.8705882
[5,] 0.8862745 0.8862745 0.8862745 0.8862745 0.8862745 0.8862745
```

The function `colorMode` can access and change the value of the slot `colormode`, modifying the rendering mode of an image. In the next example, the `Color` image `lenac` with one frame is changed into a `Grayscale` image with 3 frames, corresponding to the red, green and blue channels. The function `colorMode` does not change the content of the image but changes only the way the image is rendered by `EImage`.

```
> colorMode(lenac) = Grayscale
> display(lenac)
```

Figure 7: `lenac`, rendered as a `Color` image and as a `Grayscale` image with 3 frames (red channel, green channel, blue channel)

The color mode of image `lenac` is reverted back to `Color`.

```
> colorMode(lenac) = Color
```

The function `channel` performs colorspace conversion and can convert `Grayscale` images into `Color` ones both ways and can extract color channels from `Color` images. Unlike `colorMode`, `channel` changes the pixel intensity values of the image. The function `rgbImage` is able to combine 3 `Grayscale` images into a `Color` one.

```
> lenak = channel(lena, 'rgb')
> lenak[236:276, 106:146, 1] = 1
> lenak[236:276, 156:196, 2] = 1
> lenak[236:276, 206:246, 3] = 1
> lenab = rgbImage(red=lena, green=flop(lena), blue=flop(lena))
```

Figure 8: `lenak`, `lenab`

5 Image filtering

Images can be linearly filtered using `filter2`. `filter2` convolves the image with a matrix filter. Linear filtering is useful to perform low-pass filtering (to blur images, remove noise, ...) and high-pass filtering (to detect edges, sharpen images, ...). Various filter shapes can be generated using `makeBrush`.

```
> flo = makeBrush(21, shape='disc', step=FALSE)^2
> flo = flo/sum(flo)
> lenaflo = filter2(lenac, flo)
> fhi = matrix(1, nc=3, nr=3)
> fhi[2,2] = -8
> lenafhi = filter2(lenac, fhi)
```

Figure 9: Low-pass filtered `lenafl0` and high-pass filtered `lenafhi`

6 Morphological operations

Binary images are images where the pixels of value 0 constitute the background and the other ones constitute the foreground. These images are subject to several non-linear mathematical operators called morphological operators, able to `erode` and `dilate` an image.

```
> ei = readImage(system.file('images', 'shapes.png', package='EBImage'))
> ei = ei[110:512,1:130]
> display(ei)
> kern = makeBrush(5, shape='diamond')
> eierode = erode(ei, kern)
> eidilat = dilate(ei, kern)
```

Figure 10: `ei` ; `eierode` ; `eidilat`

7 Segmentation

Segmentation consists in extracting objects from an image. The function `bwlabel` is a simple function able to extract every connected sets of pixels from an image and relabel these sets with a unique increasing integer. `bwlabel` can be used on binary images and is useful after thresholding.

```
> eilabel = bwlabel(ei)
> cat('Number of objects=', max(eilabel), '\n')
```

Number of objects= 7

```
> nuct = nuc[:,1]>0.2
> nuclabel = bwlabel(nuct)
> cat('Number of nuclei=', max(nuclabel), '\n')
```

Number of nuclei= 74

Figure 11: `ei`, `eilabel/max(eilabel)`

Since the images `eilabel` and `nuclabel` range from 0 to the number of object they contain (given by `max(eilabel)` and `max(nucabel)`), they have to be divided by these number before displaying, in order to fit the `[0,1]` range needed by `display`.

The grayscale top-bottom gradient observable in `eilabel` and `nuclabel` is due to the way `bwlabel` labels the connected sets, from top-left to bottom-right.

Figure 12: `nuc[, ,1], nuclabel/max(nuclabel)`

Adaptive thresholding consists in comparing the intensity of pixels with their neighbors, where the neighborhood is specified by a filter matrix. The function `thresh` performs a fast adaptive thresholding of an image with a rectangular window while the combination of `filter2` and `<` allows a finer control. Adaptive thresholding allows a better segmentation when objects are close together.

```
> nuct2 = thresh(nuc[, ,1], w=10, h=10, offset=0.05)
> kern = makeBrush(5, shape='disc')
> nuct2 = dilate(erode(nuct2, kern), kern)
> nuclabel2 = bwlabel(nuct2)
> cat('Number of nuclei=', max(nuclabel2), '\n')
```

```
Number of nuclei= 77
```

Figure 13: `nuc[:, 1], nuclabel2/max(nuclabel1)`

8 Object manipulation

Objects, defined as sets of pixels with the same unique integer value can be outlined and painted using `paintObjects`. Some holes are present in objects of `nuclabel2` which can be filled using `fillHull`.

```
> nucgray = channel(nuc[, 1], 'rgb')
> nuch1 = paintObjects(nuclabel2, nucgray, col='#ff00ff')
> nuclabel3 = fillHull(nuclabel2)
> nuch2 = paintObjects(nuclabel3, nucgray, col='#ff00ff')
```

Figure 14: `nuch1, nuch2`

A broad variety of objects features (basic, image moments, shape, Haralick features) can be computed using `computeFeatures`. In particular, object coordinates are computed with the function `computeFeatures.moment`.

```
> xy = computeFeatures.moment(nuclabel3)[, c("m.cx", "m.cy")]
> xy[1:4,]
```

	m.cx	m.cy
1	122.37079	2.808989
2	211.70062	4.910494
3	497.94009	5.474654
4	16.75851	22.907121

9 Cell segmentation example

This is a complete example of segmentation of cells (nucleus + cell bodies) using the functions described before and the function `propagate`, able to perform Voronoi-based region segmentation.

Images of nuclei and cell bodies are first loaded:

```
> nuc = readImage(system.file('images', 'nuclei.tif', package='EBImage'))

image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no

> cel = readImage(system.file('images', 'cells.tif', package='EBImage'))

image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no
image 510 x 510 x 0, tiles 0 x 0, bps = 8, spp = 1 (output 1), config = 1, colormap = no

> img = rgbImage(green=1.5*cel, blue=nuc)
```

Figure 15: nuc

Figure 16: cel

Nuclei are first segmented using `thresh`, `fillHull`, `bwlabel` and `opening`, which is an `erosion` followed by a `dilatation`.

```
> nmask = thresh(nuc, w=10, h=10, offset=0.05)
> nmask = opening(nmask, makeBrush(5, shape='disc'))
> nmask = fillHull(nmask)
> nmask = bwlabel(nmask)
```

Cell bodies are segmented using `propagate`.

Figure 17: `img`

Figure 18: `nmask/max(nmask)`

Figure 19: `cmask/max(cmask)`

```
> ctmask = opening(cel>0.1, makeBrush(5, shape='disc'))
> cmask = propagate(cel, seeds=nmask, mask=ctmask)
```

Cells are outlined using `paintObjects`.

```
> res = paintObjects(cmask, img, col='#ff00ff')
> res = paintObjects(nmask, res, col='#ffff00')
```

Figure 20: Final segmentation **res**
