# Package 'universalmotif'

April 12, 2022

Title Import, Modify, and Export Motifs with R

Version 1.12.4

URL https://bioconductor.org/packages/universalmotif/

# BugReports https://github.com/bjmt/universalmotif/issues

**Description** Allows for importing most common motif types into R for use by functions provided by other Bioconductor motif-related packages. Motifs can be exported into most major motif formats from various classes as defined by other Bioconductor packages. A suite of motif and sequence manipulation and analysis functions are included, including enrichment, comparison, P-value calculation, shuffling, trimming, higher-order motifs, and others.

**Depends** R (>= 3.5.0)

License GPL-3

**Encoding** UTF-8

- Imports methods, stats, utils, MASS, ggplot2, yaml, IRanges, Rcpp, Biostrings, BiocGenerics, S4Vectors, rlang, grid
- Suggests spelling, knitr, bookdown, TFBSTools, rmarkdown, MotifDb, testthat, BiocParallel, seqLogo, motifStack, dplyr, ape, ggtree, processx, ggseqlogo, cowplot, GenomicRanges, ggbio

Enhances PWMEnrich, rGADEM

LinkingTo Rcpp, RcppThread

VignetteBuilder knitr

biocViews MotifAnnotation, MotifDiscovery, DataImport, GeneRegulation

RoxygenNote 7.1.2

**Roxygen** list(markdown = TRUE, old\_usage = TRUE)

# Index

add\_multifreq

Add multi-letter information to a motif.

# Description

If the original sequences are available for a particular motif, then they can be used to generate higher-order PPM matrices. See the "Motif import, export, and manipulation" vignette for more information.

# Usage

```
add_multifreq(motif, sequences, add.k = 2:3, RC = FALSE,
    threshold = 0.001, threshold.type = "pvalue", motifs.perseq = 1,
    add.bkg = FALSE)
```

3

### Arguments

motif	See convert_motifs() for acceptable formats. If the motif is not a univer- salmotif motif, then it will be converted.
sequences	XStringSet The alphabet must match that of the motif. If these sequences are all the same length as the motif, then they are all used to generate the multi-freq matrices. Otherwise scan_sequences() is first run to find the best sequence stretches within these.
add.k	numeric(1) The k-let lengths to add.
RC	logical(1) If TRUE, check reverse complement of the input sequences. Only available for DNA/RNA.
threshold	numeric(1) See details.
threshold.type	<pre>character(1) One of c('pvalue','qvalue','logodds','logodds.abs'). See details.</pre>
motifs.perseq	numeric(1) If scan_sequences() is run, then this indicates how many hits from each sequence is to be used.
add.bkg	logical(1) Indicate whether to add corresponding higher order background information to the motif. Can sometimes be detrimental when the input consists of few short sequences, which can increase the likelihood of adding zero or near-zero probabilities.

# Details

See scan\_sequences() for more info on scanning parameters.

At each position in the motif, then the probability of each k-let covering from the initial position to ncol -1 is calculated. Only positions within the motif are considered: this means that the final k-let probability matrix will have ncol -1 fewer columns. Calculating k-let probabilities for the missing columns would be trivial however, as you would only need the background frequencies. Since these would not be useful for scan\_sequences() though, they are not calculated.

Currently add\_multifreq() does not try to stay faithful to the default motif matrix when generating multifreq matrices. This means that if the sequences used for training are completely different from the actual motif, the multifreq matrices will be as well. However this is only really a problem if you supply add\_multifreq() with a set of sequences of the same length as the motif. In this case add\_multifreq() is forced to create the multifreq matrices from these sequences. Otherwise add\_multifreq() will scan the input sequences for the motif and use the best matches to construct the multifreq matrices.

This 'multifreq' representation is only really useful within the **universalmotif** environment. Despite this, if you wish it can be preserved in text using write\_motifs().

### A note on motif size:

The number of rows for each k-let matrix is n<sup>k</sup>, with n being the number of letters in the alphabet being used. This means that the size of the k-let matrix can become quite large as k increases. For example, if one were to wish to represent a DNA motif of length 10 as a 10-let, this would require a matrix with 1,048,576 rows (though at this point if what you want is to search for exact sequence matches, the motif format itself is not very useful).

# ArabidopsisMotif

# Value

A universalmotif object with filled multifreq slot. The bkg slot is also expanded with corresponding higher order probabilities if add.bkg = TRUE.

# Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

# See Also

```
scan_sequences(), convert_motifs(), write_motifs()
```

### Examples

```
sequences <- create_sequences(seqlen = 10)
motif <- create_motif()
motif.trained <- add_multifreq(motif, sequences, add.k = 2:4)
## peek at the 2-let matrix:
motif.trained["multifreq"]$`2`</pre>
```

ArabidopsisMotif Arabidopsis motif in universalmotif format.

# Description

Arabidopsis motif trained from ArabidopsisPromoters using MEME version 4. This motif was generated at the command line using the following command: meme promoters.fa -revcomp - nmotifs 3 -mod anr -dna.

# Usage

```
ArabidopsisMotif
```

# Format

universalmotif

ArabidopsisPromoters Arabidopsis promoters as a DNAStringSet.

### Description

50 Arabidopsis promoters, each 1000 bases long. See the "Sequence manipulation and scanning" vignette for an example workflow describing extracting promoter sequences.

### Usage

ArabidopsisPromoters

### Format

DNAStringSet

compare\_motifs Compare motifs.

# Description

Compare motifs using one of the several available metrics. See the "Motif comparisons and P-values" vignette for detailed information.

#### Usage

```
compare_motifs(motifs, compare.to, db.scores, use.freq = 1,
    use.type = "PPM", method = "PCC", tryRC = TRUE, min.overlap = 6,
    min.mean.ic = 0.25, min.position.ic = 0, relative_entropy = FALSE,
    normalise.scores = FALSE, max.p = 0.01, max.e = 10, nthreads = 1,
    score.strat = "a.mean", output.report, output.report.max.print = 10)
```

motifs	See convert_motifs() for acceptable motif formats.
compare.to	numeric If missing, compares all motifs to all other motifs. Otherwise compares all motifs to the specified motif(s).
db.scores	data.frame or DataFrame. See details.
use.freq	numeric(1). For comparing the multifreq slot.
use.type	<pre>character(1) One of 'PPM' and 'ICM'. The latter allows for taking into ac- count the background frequencies if relative_entropy = TRUE. Note that 'ICM' is not allowed when method = c("ALLR", "ALLR_LL").</pre>
method	character(1) One of PCC, EUCL, SW, KL, ALLR, BHAT, HELL, SEUCL, MAN, ALLR_LL, WEUCL, WPCC. See details.

tryRC	logical(1) Try the reverse complement of the motifs as well, report the best score.
min.overlap	numeric(1) Minimum overlap required when aligning the motifs. Setting this to a number higher then the width of the motifs will not allow any overhangs. Can also be a number between 0 and 1, representing the minimum fraction that the motifs must overlap.
<pre>min.mean.ic min.position.id</pre>	<pre>numeric(1) Minimum mean information content between the two motifs for an alignment to be scored. This helps prevent scoring alignments between low information content regions of two motifs. Note that this can result in some comparisons failing if no alignment passes the mean IC threshold. Use average_ic() to filter out low IC motifs to get around this if you want to avoid getting NAs in your output.</pre>
min.posicion.ic	
	numeric(1) Minimum information content required between individual align- ment positions for it to be counted in the final alignment score. It is recom- mended to use this together with normalise.scores = TRUE, as this will help punish scores resulting from only a fraction of an alignment.
relative_entrop	
	<pre>logical(1) Change the ICM calculation affecting min.position.ic and min.mean.ic. See convert_type().</pre>
normalise.score	
	logical(1) Favour alignments which leave fewer unaligned positions, as well as alignments between motifs of similar length. Similarity scores are multiplied by the ratio of aligned positions to the total number of positions in the larger motif, and the inverse for distance scores.
max.p	numeric(1) Maximum P-value allowed in reporting matches. Only used if compare.to is set.
max.e	numeric(1) Maximum E-value allowed in reporting matches. Only used if compare.to is set. The E-value is the P-value multiplied by the number of input motifs times two.
nthreads	<pre>numeric(1) Run compare_motifs() in parallel with nthreads threads. nthreads = 0 uses all available threads.</pre>
score.strat	character(1) How to handle column scores calculated from motif alignments. "sum": add up all scores. "a.mean": take the arithmetic mean. "g.mean": take the geometric mean. "median": take the median. "wa.mean", "wg.mean": weighted arithmetic/geometric mean. "fzt": Fisher Z-transform. Weights are the total information content shared between aligned columns.
output.report	character(1) Provide a filename for compare_motifs() to write an html ouput report to. The top matches are shown alongside figures of the match alignments. This requires the knitr and rmarkdown packages. (Note: still in development.)
output.report.max.print	
	numeric(1) Maximum number of top matches to print.

# Details

# Available metrics:

The following metrics are available:

- Euclidean distance (EUCL) (Choi et al. 2004)
- Weighted Euclidean distance (WEUCL)
- Kullback-Leibler divergence (KL) (Kullback and Leibler 1951; Roepcke et al. 2005)
- Hellinger distance (HELL) (Hellinger 1909)
- Squared Euclidean distance (SEUCL)
- Manhattan distance (MAN)
- Pearson correlation coefficient (PCC)
- Weighted Pearson correlation coefficient (WPCC)
- Sandelin-Wasserman similarity (SW), or sum of squared distances (Sandelin and Wasserman 2004)
- Average log-likelihood ratio (ALLR) (Wang and Stormo 2003)
- Lower limit ALLR (ALLR\_LL) (Mahony et al. 2007)
- Bhattacharyya coefficient (BHAT) (Bhattacharyya 1943)

Comparisons are calculated between two motifs at a time. All possible alignments are scored, and the best score is reported. In an alignment scores are calculated individually between columns. How those scores are combined to generate the final alignment scores depends on score.strat. See the "Motif comparisons and P-values" vignette for a description of the various metrics. Note that PCC, WPCC, SW, ALLR, ALLR\_LL and BHAT are similarities; higher values mean more similar motifs. For the remaining metrics, values closer to zero represent more similar motifs.

Small pseudocounts are automatically added when one of the following methods is used: KL, ALLR, ALLR\_LL, IS. This is avoid zeros in the calculations.

# **Calculating P-values:**

To note regarding p-values: P-values are pre-computed using the make\_DBscores() function. If not given, then uses a set of internal precomputed P-values from the JASPAR2018 CORE motifs. These precalculated scores are dependent on the length of the motifs being compared. This takes into account that comparing small motifs with larger motifs leads to higher scores, since the probability of finding a higher scoring alignment is higher.

The default P-values have been precalculated for regular DNA motifs. They are of little use for motifs with a different number of alphabet letters (or even the multifreq slot).

# Value

matrix if compare.to is missing; DataFrame otherwise. For the latter, function args are stored in the metadata slot.

# Examples

```
motif1 <- create_motif(name = "1")</pre>
motif2 <- create_motif(name = "2")</pre>
motif1vs2 <- compare_motifs(c(motif1, motif2), method = "PCC")</pre>
## To get a dist object:
as.dist(1 - motif1vs2)
motif3 <- create_motif(name = "3")</pre>
motif4 <- create_motif(name = "4")</pre>
motifs <- c(motif1, motif2, motif3, motif4)</pre>
## Compare motif "2" to all the other motifs:
if (R.Version()$arch != "i386") {
compare_motifs(motifs, compare.to = 2, max.p = 1, max.e = Inf)
}
## If you are working with a large list of motifs and the mean.min.ic
## option is not set to zero, you may get a number of failed comparisons
## due to low IC. To filter the list of motifs to avoid these, use
## the average_ic() function to remove motifs with low average IC:
```

```
library(MotifDb)
motifs <- convert_motifs(MotifDb)[1:100]
compare_motifs(motifs)
#> Warning in compare_motifs(motifs) :
#> Some comparisons failed due to low IC
motifs <- motifs[average_ic(motifs) > 0.5]
compare_motifs(motifs)
```

## End(Not run)

convert\_motifs Convert motif class.

### Description

Allows for easy transfer of motif information between different classes as defined by other Bioconductor packages. This function is also used by nearly all other functions in this package, so any motifs of a compatible class can be used without needing to be converted beforehand.

#### Usage

```
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'AsIs'
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'list'
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'universalmotif'
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'MotifList'
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'TFFMFirst'
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'PFMatrix'
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'PWMatrix'
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'ICMatrix'
convert_motifs(motifs, class = "universalmotif-universalmotif")
```

10

```
## S4 method for signature 'XMatrixList'
convert_motifs(motifs, class = "universalmotif-universalmotif")
## S4 method for signature 'pwm'
convert_motifs(motifs, class = "universalmotif-universalmotif")

convert_motifs(motifs, class = "universalmotif-universalmotif")
```

```
## S4 method for signature 'matrix'
convert_motifs(motifs, class = "universalmotif-universalmotif")
```

### Arguments

motifs	Single motif object or list. See details.
class	character(1) Desired motif class. Input as 'package-class'. If left empty, defaults to 'universalmotif-universalmotif'. (See details.)

# Details

### Input:

The following packge-class combinations can be used as input:

- MotifDb-MotifList
- TFBSTools-PFMatrix
- TFBSTools-PWMatrix
- TFBSTools-ICMatrix
- TFBSTools-PFMatrixList
- TFBSTools-PWMatrixList
- TFBSTools-ICMatrixList
- TFBSTools-TFFMFirst
- seqLogo-pwm
- motifStack-pcm
- motifStack-pfm
- PWMEnrich-PWM
- motifRG-Motif
- universalmotif-universalmotif

• matrix

### **Output:**

The following package-class combinations can be output:

- TFBSTools-PFMatrix
- TFBSTools-PWMatrix
- TFBSTools-ICMatrix
- TFBSTools-TFFMFirst
- seqLogo-pwm
- motifStack-pcm
- motifStack-pfm
- PWMEnrich-PWM
- Biostrings-PWM (type = 'log2prob')
- rGADEM-motif
- universalmotif-universalmotif (the default, no need to specify this)

Note: MotifDb-MotifList output was a later addition to convert\_motifs(). As a result, to stay consistent with previous behaviour most functions will always convert MotifDb-MotifList objects to a list of universalmotif motifs, even if other formats would be simply returned as is (e.g. for other formats, filter\_motifs() will return the input format; for MotifDb-MotifList, a list of universalmotif objects will be returned).

# Value

Single motif object or list.

# Methods (by class)

- AsIs: Generate an error to remind users to run to\_list() instead of using the column from to\_df() directly.
- list: Convert a list of motifs.
- universalmotif: Convert a universalmotif object.
- MotifList: Convert MotifList motifs. (MotifDb)
- TFFMFirst: Convert TFFMFirst motifs. (TFBSTools)
- PFMatrix: Convert PFMatrix motifs. (TFBSTools)
- PWMatrix: Convert PWMatrix motifs. (TFBSTools)
- ICMatrix: Convert ICMatrix motifs. (TFBSTools)
- XMatrixList: Convert XMatrixList motifs. (TFBSTools)
- pwm: Convert pwm motifs. (seqLogo)
- pcm: Convert pcm motifs. (motifStack)
- pfm: Convert pfm motifs. (motifStack)
- PWM: Convert PWM motifs. (PWMEnrich)
- Motif: Convert Motif motifs. (motifRG)
- matrix: Create motif from matrices.

# Note: if the motif object going in has information that the
# 'universalmotif' class can't hold, it will be lost
}
```

convert\_type

### Description

Switch between position count matrix (PCM), position probability matrix (PPM), position weight matrix (PWM), and information count matrix (ICM) types. See the "Introduction to sequence motifs" vignette for details. Please also note that type conversion occurs implicitly throughout the universalmotif package, so there is generally no need to perform this manual conversion. Also please be aware that the message concerning pseudocount-adjusting motifs can be disabled via options (pseudocount.warning=FALSE).

### Usage

```
convert_type(motifs, type, pseudocount, nsize_correction = FALSE,
    relative_entropy = FALSE)
```

# Arguments

motifs	See convert_motifs() for acceptable formats.	
type	<pre>character(1) One of c('PCM','PPM','PWM','ICM').</pre>	
pseudocount	numeric(1) Correction to be applied to prevent -Inf from appearing in PWM matrices. If missing, the pseudocount stored in the universalmotif 'pseudocount' slot will be used.	
nsize_correction		
	logical(1) If true, the ICM at each position will be corrected to account for small sample sizes. Only used if relative_entropy = FALSE.	

relative\_entropy

logical(1) If true, the ICM will be calculated as relative entropy. See details.

# Details

# PCM:

Position count matrix (PCM), also known as position frequency matrix (PFM). For n sequences from which the motif was built, each position is represented by the numbers of each letter at that position. In theory all positions should have sums equal to n, but not all databases are this consistent. If converting from another type to PCM, column sums will be equal to the 'nsites' slot. If empty, 100 is used.

### PPM:

Position probability matrix (PPM), also known as position frequency matrix (PFM). At each position, the probability of individual letters is calculated by dividing the count for that letter by the total sum of counts at that position (letter\_count / position\_total). As a result, each position will sum to 1. Letters with counts of 0 will thus have a probability of 0, which can be undesirable when searching for motifs in a set of sequences. To avoid this a pseudocount can be added ((letter\_count + pseudocount) / (position\_total + pseudocount)).

### PWM:

Position weight matrix (PWM; Stormo et al. (1982)), also known as position-specific weight matrix (PSWM), position-specific scoring matrix (PSSM), or log-odds matrix. At each position, each letter is represented by it's log-likelihood (log2(letter\_probability / background\_probility)), which is normalized using the background letter frequencies. A PWM matrix is constructed from a PPM. If any position has 0-probability letters to which pseudocounts were not added, then the final log-likelihood of these letters will be -Inf.

### ICM:

Information content matrix (ICM; Schneider and Stephens 1990). An ICM is a PPM where each letter probability is multiplied by the total information content at that position. The information content of each position is determined as: totalIC -Hi, where the total information totalIC

totalIC <-log2(alphabet\_length), and the Shannon entropy (Shannon 1948) for a specific position (Hi)

Hi <- -sum(sapply(alphabet\_frequencies, function(x) x \* log(2)).

As a result, the total sum or height of each position is representative of it's sequence conservation, measured in the unit 'bits', which is a unit of energy (Schneider 1991; see https://fr-s-schneider.ncifcrf.gov/logorecommendations.html for more information). However not all programs will calculate information content the same. Some will 'correct' the total information content at each position using a correction factor as described by Schneider et al. (1986). This correction can applied by setting nsize\_correction = TRUE, however it will only be applied if the 'nsites' slot is not empty. This is done using TFBSTools:::schneider\_correction (Tan and Lenhard 2016). As such, converting from an ICM to which some form of correction has been applied will result in a PCM/PPM/PWM with slight inaccuracies.

Another method of calculating information content is calculating the relative entropy, also known as Kullback-Leibler divergence (Kullback and Leibler 1951). This accounts for background frequencies, which can be useful for genomes with a heavy imbalance in letter frequencies. For each position, the individual letter frequencies are calculated as letter\_freq \* log2(letter\_freq / bkg\_freq). When calculating information content using Shannon entropy, the maximum content for each position will always be log2(alphabet\_length). This does not hold for information content calculated as relative entropy. Please note that conversion from ICM assumes the information content was *not* calculated as relative entropy.

### Value

See convert\_motifs() for possible output motif objects.

### Examples

create\_motif Create a motif.

### Description

Create a motif from a set of sequences, a matrix, or generate a random motif. See the "Motif import, export and manipulation" vignette for details.

# Usage

```
create_motif(input, alphabet, type = "PPM", name = "motif",
    pseudocount = 0, bkg, nsites, altname, family, organism, bkgsites, strand,
    pval, qval, eval, extrainfo, add.multifreq)
## S4 method for signature 'missing'
create_motif(input, alphabet, type = "PPM",
```

16

```
name = "motif", pseudocount = 0, bkg, nsites, altname, family, organism,
 bkgsites, strand, pval, qval, eval, extrainfo, add.multifreq)
## S4 method for signature 'numeric'
create_motif(input, alphabet, type = "PPM",
  name = "motif", pseudocount = 0, bkg, nsites, altname, family, organism,
 bkgsites, strand, pval, qval, eval, extrainfo, add.multifreq)
## S4 method for signature 'character'
create_motif(input, alphabet, type = "PPM",
  name = "motif", pseudocount = 0, bkg, nsites, altname, family, organism,
 bkgsites, strand, pval, qval, eval, extrainfo, add.multifreq)
## S4 method for signature 'matrix'
create_motif(input, alphabet, type = "PPM",
  name = "motif", pseudocount = 0, bkg, nsites, altname, family, organism,
 bkgsites, strand, pval, qval, eval, extrainfo, add.multifreq)
## S4 method for signature 'DNAStringSet'
create_motif(input, alphabet, type = "PPM",
  name = "motif", pseudocount = 0, bkg, nsites, altname, family, organism,
 bkgsites, strand, pval, qval, eval, extrainfo, add.multifreq)
## S4 method for signature 'RNAStringSet'
create_motif(input, alphabet, type = "PPM",
  name = "motif", pseudocount = 0, bkg, nsites, altname, family, organism,
 bkgsites, strand, pval, qval, eval, extrainfo, add.multifreq)
## S4 method for signature 'AAStringSet'
create_motif(input, alphabet, type = "PPM",
  name = "motif", pseudocount = 0, bkg, nsites, altname, family, organism,
 bkgsites, strand, pval, qval, eval, extrainfo, add.multifreq)
## S4 method for signature 'BStringSet'
create_motif(input, alphabet, type = "PPM",
  name = "motif", pseudocount = 0, bkg, nsites, altname, family, organism,
  bkgsites, strand, pval, qval, eval, extrainfo, add.multifreq)
```

input	character, numeric, matrix, XStringSet, or missing.
alphabet	character(1) One of c('DNA', 'RNA', 'AA'), or a combined string represent- ing the letters. If no alphabet is provided then it will try and guess the alphabet from the input.
type	character(1) One of c('PCM','PPM','PWM','ICM').
name	character(1) Motif name.
pseudocount	numeric(1) Correction to be applied to prevent -Inf from appearing in PWM matrices. Defaults to 0.

bkg	numeric A vector of probabilities, each between 0 and 1. If higher order back- grounds are provided, then the elements of the vector must be named. If un- named, then the order of probabilities must be in the same order as the alphabet- ically sorted sequence alphabet.
nsites	numeric(1) Number of sites the motif was constructed from. If blank, then create_motif() will guess the appropriate number if possible. To prevent this, provide nsites = numeric().
altname	character(1) Alternate motif name.
family	character(1) Transcription factor family.
organism	character(1) Species of origin.
bkgsites	numeric(1) Total number of sites used to find the motif.
strand	character(1) Whether the motif is specific to a certain strand. Acceptable strands are '+', '-', and '+-' (to represent both strands). Note that '-+' and '*' can also be provided to represent both strands, but the final strand in the universalmotif object will be set to '+-'.
pval	numeric(1) P-value associated with motif.
qval	numeric(1) Adjusted P-value associated with motif.
eval	numeric(1) E-value associated with motif.
extrainfo	character Any other extra information, represented as a named character vec- tor.
add.multifreq	<pre>numeric If the motif is created from a set of sequences, then the add_multifreq() function can be run at the same time (with RC = FALSE).</pre>

# Details

The aim of this function is provide an easy interface to creating universalmotif motifs, as an alternative to the default class constructor (i.e. new('universalmotif', name=...)). See examples for potential use cases.

Note: when generating random motifs, the nsites slot is also given a random value.

See the examples section for more info on motif creation.

# Value

universalmotif object.

# Methods (by class)

- missing: Create a random motif of length 10.
- numeric: Create a random motif with a specified length.
- character: Create motif from a consensus string.
- matrix: Create motif from a matrix.
- DNAStringSet: Create motif from a DNAStringSet.
- RNAStringSet: Create motif from a RNAStringSet.
- AAStringSet: Create motif from a AAStringSet.
- BStringSet: Create motif from a BStringSet.

### create\_motif

custom.motif <- create_motif(mat)</pre>
# Matrices can also be used as input
mat.ppm <- matrix(c(0.1, 0.1, 0.1, 0.1,</pre>
                     0.5, 0.5, 0.5, 0.5,
                     0.1, 0.1, 0.1, 0.1,
                      0.3, 0.3, 0.3, 0.3),
                     nrow = 4, byrow = TRUE)
DNA.motif <- create_motif(mat.ppm, alphabet = "DNA", type = "PPM")
##### Create random motifs
# These are generated as PPMs with 10 positions
```

## End(Not run)

```
DNA.motif <- create_motif()
RNA.motif <- create_motif(alphabet = "RNA")
AA.motif <- create_motif(alphabet = "AA")
custom.motif <- create_motif(alphabet = "QWER")
# The number of positions can be specified
DNA.motif <- create_motif(5)
# If the background frequencies are not provided, they are generated
# using `rpois`; positions are created using `rdirichlet(1, bkg)`.
# (calling `create_motif()` creates motifs with an average
# positional IC of 1)
DNA.motif <- create_motif(10, bkg = c(0.1, 0.4, 0.4, 0.1))</pre>
```

create\_sequences Create random sequences.

### Description

Generate random sequences from any set of characters, represented as XStringSet objects.

# Usage

```
create_sequences(alphabet = "DNA", seqnum = 100, seqlen = 100, freqs,
    nthreads = 1, rng.seed = sample.int(10000, 1))
```

alphabet	character(1) One of c('DNA', 'RNA', 'AA'), or a string of characters to be used as the alphabet.
seqnum	numeric(1) Number of sequences to generate.
seqlen	numeric(1) Length of random sequences.
freqs	numeric A named vector of probabilities. The length of the vector must be the power of the number of letters in the sequence alphabet. Probabilities can only be provided for a single size k.
nthreads	<pre>numeric(1) Run create_sequences() in parallel with nthreads threads. nthreads = 0 uses all available threads. Note that no speed up will occur for jobs with seqnum = 1.</pre>
rng.seed	numeric(1) Set random number generator seed. Since sequence creation can occur simultaneously in multiple threads using C++, it cannot communicate with the regular R random number generator state and thus requires an independent seed. Each individual sequence creation instance is given the following

seed: rng.seed \* index. The default is to pick a random number as chosen by
sample(), which effectively is making create\_sequences() dependent on the
R RNG state.

#### Value

XStringSet The returned sequences are *unnamed*.

### See Also

create\_motif(), shuffle\_sequences()

#### Examples

```
## Create DNA sequences with slightly increased AT content:
sequences <- create_sequences(freqs = c(A=0.3, C=0.2, G=0.2, T=0.3))
## Create custom sequences:
sequences.QWER <- create_sequences("QWER")
## You can include non-alphabet characters are well, even spaces:
sequences.custom <- create_sequences("!@#$ ")</pre>
```

enrich_motifs	Enrich for input motifs in a set of sequences.

### Description

Given a set of target and background sequences, test if the input motifs are significantly enriched in the targets sequences relative to the background sequences. See the "Sequence manipulation and scanning" vignette.

### Usage

```
enrich_motifs(motifs, sequences, bkg.sequences, max.p = 1e-05,
max.q = 1e-05, max.e = 0.001, qval.method = "fdr", threshold = 1e-04,
threshold.type = "pvalue", verbose = 0, RC = FALSE, use.freq = 1,
shuffle.k = 2, shuffle.method = "euler", return.scan.results = FALSE,
nthreads = 1, rng.seed = sample.int(10000, 1), motif_pvalue.k = 8,
use.gaps = TRUE, allow.nonfinite = FALSE, warn.NA = TRUE,
no.overlaps = FALSE, no.overlaps.by.strand = FALSE,
no.overlaps.strat = "score", respect.strand = FALSE,
motif_pvalue.method = c("dynamic", "exhaustive"),
scan_sequences.qvals.method = c("BH", "fdr", "bonferroni"))
```

# enrich\_motifs

motifs	See convert_motifs() for acceptable motif formats.	
sequences	XStringSet Sequences to scan. Alphabet should match motif.	
bkg.sequences	XStringSet Optional. If missing, shuffle_sequences() is used to create background sequences from the input sequences.	
max.p	numeric(1) P-value threshold.	
max.q	numeric(1) Adjusted P-value threshold. This is only useful if multiple motifs are being enriched for.	
max.e	numeric(1). The E-value is calculated by multiplying the adjusted P-value with the number of input motifs times two (McLeay and Bailey 2010).	
qval.method	<pre>character(1) See stats::p.adjust().</pre>	
threshold	numeric(1) See details.	
threshold.type	<pre>character(1) One of c('pvalue','qvalue','logodds','logodds.abs'). See details.</pre>	
verbose	numeric(1) 0 for no output, 4 for max verbosity.	
RC	logical(1) If TRUE, check reverse complement of the input sequences. Only available for DNA/RNA.	
use.freq	numeric(1) The default, 1, uses the motif matrix (from the motif['motif'] slot) to search for sequences. If a higher number is used, then the matching k-let matrix from the motif['multifreq'] slot is used. See add_multifreq().	
shuffle.k	numeric(1) The k-let size to use when shuffling input sequences. Only used if no background sequences are input. See shuffle_sequences().	
<pre>shuffle.method</pre>	<pre>character(1) One of c('euler', 'markov', 'linear'). See shuffle_sequences().</pre>	
return.scan.results		
	logical(1) Return output from scan_sequences(). For large jobs, leaving this as FALSE can save a small amount time by preventing construction of the complete results data.frame from scan_sequences().	
nthreads	<pre>numeric(1) Run scan_sequences() in parallel with nthreads threads. nthreads = 0 uses all available threads. Note that no speed up will occur for jobs with only a single motif and sequence.</pre>	
rng.seed	<pre>numeric(1) Set random number generator seed. Since shuffling can occur si- multaneously in multiple threads using C++, it cannot communicate with the regular R random number generator state and thus requires an independent seed. Each individual sequence in an XStringSet object will be given the following seed: rng.seed * index. See shuffle_sequences().</pre>	
<pre>motif_pvalue.k</pre>	<pre>numeric(1) Control motif_pvalue() approximation. See motif_pvalue().</pre>	
use.gaps	logical(1) Set this to FALSE to ignore motif gaps, if present.	
allow.nonfinite		
	logical(1) If FALSE, then apply a pseudocount if non-finite values are found in the PWM. Note that if the motif has a pseudocount greater than zero and the motif is not currently of type PWM, then this parameter has no effect as the pseudocount will be applied automatically when the motif is converted to a	

		PWM internally. This value is set to FALSE by default in order to stay consistent with pre-version 1.8.0 behaviour. A message will be printed if a pseudocount is applied. To disable this, set options(pseudocount.warning=FALSE).
warn	. NA	logical(1) Whether to warn about the presence of non-standard letters in the input sequence, such as those in masked sequences.
no.o	verlaps	logical(1) Remove overlapping hits from the same motifs. Overlapping hits from different motifs are preserved. Please note that the current implementation of this feature can add significantly to the run time for large inputs.
no.o	verlaps.by.	strand
		logical(1) Whether to discard overlapping hits from the opposite strand, or to only discard overlapping hits on the same strand.
no.o	verlaps.str	at
		character(1) One of c("score", "order"). The former option keeps the highest scoring overlapping hit (and the first of these within ties), and the latter simply keeps the first overlapping hit.
resp	ect.strand	logical(1) If motifs are DNA/RNA, then setting this option to TRUE will make scan_sequences() only scan the strands of the input sequences as indicated in the motif strand slot.
moti	f_pvalue.me	thod
		character(1) One of c("dynamic", "exhaustive"). Algorithm used for cal- culating P-values. The "exhaustive" method involves finding all possible mo- tif matches at or above the specified score using a branch-and-bound algorithm, which can be computationally intensive (Hartman et al., 2013). Additionally, the computation must be repeated for each hit. The "dynamic" method cal- culates the distribution of possible motif scores using a much faster dynamic programming algorithm, and can be recycled for multiple scores (Grant et al., 2011). The only disadvantage is the inability to use allow.nonfinite = TRUE. See motif_pvalue() for details.
scan	_sequences.	qvals.method
		character(1) One of c("fdr", "BH", "bonferroni"). The method for calcu- lating adjusted P-values for individual motif hits. These are described in depth in the Sequence Searches vignette.

# Details

To find enriched motifs, scan\_sequences() is run on both target and background sequences. stats::fisher.test() is run to test for enrichment.

See scan\_sequences() for more info on scanning parameters.

# Value

DataFrame Enrichment results in a DataFrame. Function args and (optionally) scan results are stored in the metadata slot.

}
```

examplemotif Example motif in universalmotif format.

# Description

A simple DNA motif. To recreate this motif: create\_motif("TATAWAW", nsites = numeric())

# Usage

examplemotif

### Format

universalmotif

examplemotif2 Another example motif in universalmotif format.

### Description

A simple DNA motif with a non-empty multifreq slot. To recreate to this motif: add\_multifreq(examplemotif,DNAStrin

#### Usage

```
examplemotif2
```

### Format

universalmotif

filter\_motifs

### Description

Filter motifs based on the contents of available universalmotif slots. If the input motifs are not of universalmotif, then they will be converted for the duration of the filter\_motifs() operation.

### Usage

```
filter_motifs(motifs, name, altname, family, organism, width, alphabet, type,
icscore, nsites, strand, pval, qval, eval, extrainfo)
```

# Arguments

motifs	list See convert_motifs() for acceptable formats.
name	character Keep motifs by names.
altname	character Keep motifs by altnames.
family	character Keep motifs by family.
organism	character Keep motifs by organism.
width	numeric(1) Keep motifs with minimum width.
alphabet	character Keep motifs by alphabet.
type	character Keep motifs by type.
icscore	numeric(1) Keep motifs with minimum total IC.
nsites	numeric(1) Keep motifs with minimum number of target sites.
strand	character Keeps motifs by strand.
pval	numeric(1) Keep motifs by max P-value.
qval	numeric(1) Keep motifs by max Q-value.
eval	numeric(1) Keep motifs by max E-val.
extrainfo	character Named character vector of items that must be present in motif extrainfo slots.

# Value

list Motifs. An attempt will be made to preserve the original class, see convert\_motifs() for limitations.

# Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

# fontDFroboto

### Examples

```
## By minimum IC:
jaspar <- read_jaspar(system.file("extdata", "jaspar.txt",</pre>
                                   package = "universalmotif"))
jaspar.ic3 <- filter_motifs(jaspar, icscore = 3)</pre>
## Starting from version 1.10.0 of the universalmotif package, one
## could instead make use of the universalmotif_df structure:
jaspar.ic3 <- jaspar |> to_df() |> subset(icscore > 3) |> to_list()
## By organism:
## Not run:
library(MotifDb)
motifs <- convert_motifs(MotifDb)</pre>
motifs <- filter_motifs(motifs, organism = c("Athaliana", "Mmusculus"),</pre>
                         extrainfo = c("dataSource" = "cisbp_1.02"))
## Or:
motifs <- convert_motifs(MotifDb) |> to_df() |>
  subset(organism %in% c("Athaliana", "Mmusculus") &
    dataSource == "cisbp_1.02") |> to_list()
```

```
## End(Not run)
```

# Description

DataFrame of polygon coordinates used by view\_motifs() for plotting letters. It was generated using the createPolygons function from the gglogo package for the font Roboto Medium.

### Usage

fontDFroboto

# Format

DataFrame

get\_bkg

# Description

For a set of input sequences, calculate the overall sequence background for any k-let size. For very large sequences DNA and RNA sequences (in the billions of bases), please be aware of the much faster and more efficient Biostrings::oligonucleotideFrequency(). get\_bkg() can still be used in these cases, though it may take several seconds or minutes to calculate the results (depending on requested k-let sizes).

# Usage

```
get_bkg(sequences, k = 1:3, as.prob = NULL, pseudocount = 0,
alphabet = NULL, to.meme = NULL, RC = FALSE, list.out = NULL,
nthreads = 1, merge.res = TRUE, window = FALSE, window.size = 0.1,
window.overlap = 0)
```

sequences	XStringSet Input sequences. Note that if multiple sequences are present, the results will be combined into one (unless merge.res = FALSE).
k	integer Size of k-let. Background can be calculated for any k-let size.
as.prob	Deprecated.
pseudocount	integer(1) Add a count to each possible k-let. Prevents any k-let from having 0 or 1 probabilities.
alphabet	character(1) Provide a custom alphabet to calculate a background for. If NULL, then standard letters will be assumed for DNA, RNA and AA sequences, and all unique letters found will be used for BStringSet type sequences. Note that letters which are not a part of the standard DNA/RNA/AA alphabets or in the provided alphabet will not be counted in the totals during probability calculations.
to.meme	If not NULL, then get_bkg() will return the sequence background in MEME Markov Background Model format. Input for this argument will be used for cat(,file = to.meme) within get_bkg(). See http://meme-suite.org/ doc/bfile-format.html for a description of the format.
RC	logical(1) Calculate the background of the reverse complement of the input sequences as well. Only valid for DNA/RNA.
list.out	Deprecated.
nthreads	numeric(1) Run get_bkg() in parallel with nthreads threads. nthreads = 0 uses all available threads. Note that no speed up will occur for jobs with only a single sequence.
merge.res	logical(1) Whether to merge results from all sequences or return background data for individual sequences.

window	logical(1) Determine background in windows.
window.size	numeric Window size. If a number between 0 and 1 is provided, the value is calculated as the number multiplied by the sequence length.
window.overlap	numeric Overlap between windows. If a number between 0 and 1 is provided, the value is calculated as the number multiplied by the sequence length.

# Value

If to.meme = NULL, a DataFrame with columns klet, count, and probability. If merge.res = FALSE, there will be an additional sequence column. If window = TRUE, there will be an additional start and stop columns.

If to.meme is not NULL, then NULL is returned, invisibly.

JASPAR2018 CORE database scores

# Description

For use with compare\_motifs(). The precomputed scores allow for fast P-value estimation. These scores were generated using make\_DBscores() with the JASPAR2018 CORE motif set. The scores are organized in a DataFrame. In this DataFrame is the location and scale of scores resulting from a statistical distribution using the the comparisons of JASPAR2018 CORE motifs with randomized motifs of the specified subject and target motif length. Created using make\_DBscores() from universalmotif v1.4.0. The parameters used can be seen via S4Vectors::metadata(JASPAR2018\_CORE\_DBSCORES).

#### Usage

JASPAR2018\_CORE\_DBSCORES

# Format

DataFrame with function args in the metadata slot.

make\_DBscores Create P-value databases.

### Description

Generate data used by compare\_motifs() for P-value calculations. By default, compare\_motifs() uses an internal database based on the JASPAR2018 core motifs (Khan et al. 2018). Parameters for distributions are are estimated for every combination of motif widths.

### Usage

```
make_DBscores(db.motifs, method = c("PCC", "EUCL", "SW", "KL", "WEUCL",
    "ALLR", "BHAT", "HELL", "WPCC", "SEUCL", "MAN", "ALLR_LL"),
    shuffle.db = TRUE, shuffle.k = 3, shuffle.method = "linear",
    rand.tries = 1000, widths = 5:30, min.position.ic = 0,
    normalise.scores = c(FALSE, TRUE), min.overlap = 6, min.mean.ic = 0.25,
    progress = TRUE, nthreads = 1, tryRC = TRUE, score.strat = c("sum",
    "a.mean", "g.mean", "median", "wa.mean", "wg.mean", "fzt"))
```

# make\_DBscores

# Arguments

db.motifs	list Database motifs.
	character(1) One of PCC, EUCL, SW, KL, ALLR, BHAT, HELL, SEUCL, MAN, ALLR_LL, WEUCL, WPCC. See details.
shuffle.db	logical(1) Deprecated. Does nothing. generate random motifs with create_motif().
shuffle.k	<pre>numeric(1) See shuffle_motifs().</pre>
shuffle.method	<pre>character(1) See shuffle_motifs().</pre>
	numeric(1) Approximate number of comparisons to perform for every combi- nation of widths.
widths	numeric Motif widths to use in P-value database calculation.
<pre>min.position.ic</pre>	
	numeric(1) Minimum information content required between individual align- ment positions for it to be counted in the final alignment score. It is recom- mended to use this together with normalise.scores = TRUE, as this will help punish scores resulting from only a fraction of an alignment.
normalise.score:	
	logical(1) Favour alignments which leave fewer unaligned positions, as well as alignments between motifs of similar length. Similarity scores are multiplied by the ratio of aligned positions to the total number of positions in the larger motif, and the inverse for distance scores.
	numeric(1) Minimum overlap required when aligning the motifs. Setting this to a number higher then the width of the motifs will not allow any overhangs. Can also be a number between 0 and 1, representing the minimum fraction that the motifs must overlap.
	numeric(1) Minimum mean information content between the two motifs for an alignment to be scored. This helps prevent scoring alignments between low information content regions of two motifs. Note that this can result in some comparisons failing if no alignment passes the mean IC threshold. Use average_ic() to filter out low IC motifs to get around this if you want to avoid getting NAs in your output.
progress	logical(1) Show progress.
	<pre>numeric(1) Run compare_motifs() in parallel with nthreads threads. nthreads = 0 uses all available threads.</pre>
-	logical(1) Try the reverse complement of the motifs as well, report the best score.
	character(1) How to handle column scores calculated from motif alignments. "sum": add up all scores. "a.mean": take the arithmetic mean. "g.mean": take the geometric mean. "median": take the median. "wa.mean", "wg.mean": weighted arithmetic/geometric mean. "fzt": Fisher Z-transform. Weights are the total information content shared between aligned columns.

# Details

See compare\_motifs() for more info on comparison parameters.

To replicate the internal **universalmotif** DB scores, run make\_DBscores() with the default settings. Note that this will be a slow process.

Arguments widths, method, normalise.scores and score.strat are vectorized; all combinations will be attempted.

### Value

A DataFrame with score distributions for the input database. If more than one make\_DBscores() run occurs (i.e. args method, normalise.scores or score.strat are longer than 1), then the function args are included in the metadata slot.

```
## Not run:
library(MotifDb)
motifs <- convert_motifs(MotifDb[1:100])
scores <- make_DBscores(motifs, method = "PCC")
compare_motifs(motifs, 1:100, db.scores = scores)
```

## End(Not run)

merge\_motifs Merge motifs.

# Description

Aligns the motifs using compare\_motifs(), then averages the motif PPMs. Currently the multifreq slot, if filled in any of the motifs, will be dropped. Only 0-order background probabilities will be kept. Motifs are merged one at a time, starting with the first entry in the list.

# merge\_motifs

# Usage

```
merge_motifs(motifs, method = "ALLR", use.type = "PPM", min.overlap = 6,
min.mean.ic = 0.25, tryRC = TRUE, relative_entropy = FALSE,
normalise.scores = FALSE, min.position.ic = 0, score.strat = "sum",
new.name = NULL)
```

motifs	See convert_motifs() for acceptable motif formats.
method	character(1) One of PCC, EUCL, SW, KL, ALLR, BHAT, HELL, SEUCL, MAN, ALLR_LL, WEUCL, WPCC. See details.
use.type	character(1) One of 'PPM' and 'ICM'. The latter allows for taking into ac- count the background frequencies if relative_entropy = TRUE. Note that 'ICM' is not allowed when method = c("ALLR", "ALLR_LL").
min.overlap	numeric(1) Minimum overlap required when aligning the motifs. Setting this to a number higher then the width of the motifs will not allow any overhangs. Can also be a number between 0 and 1, representing the minimum fraction that the motifs must overlap.
min.mean.ic	numeric(1) Minimum mean information content between the two motifs for an alignment to be scored. This helps prevent scoring alignments between low information content regions of two motifs. Note that this can result in some comparisons failing if no alignment passes the mean IC threshold. Use average_ic() to filter out low IC motifs to get around this if you want to avoid getting NAs in your output.
tryRC	logical(1) Try the reverse complement of the motifs as well, report the best score.
relative_entrop	
	<pre>logical(1) Change the ICM calculation affecting min.position.ic and min.mean.ic. See convert_type().</pre>
normalise.score	See convert_type().
normalise.score	See convert_type().
normalise.score	See convert_type(). es logical(1) Favour alignments which leave fewer unaligned positions, as well as alignments between motifs of similar length. Similarity scores are multiplied by the ratio of aligned positions to the total number of positions in the larger motif, and the inverse for distance scores.
	See convert_type(). es logical(1) Favour alignments which leave fewer unaligned positions, as well as alignments between motifs of similar length. Similarity scores are multiplied by the ratio of aligned positions to the total number of positions in the larger motif, and the inverse for distance scores. numeric(1) Minimum information content required between individual alignment positions for it to be counted in the final alignment score. It is recommended to use this together with normalise.scores = TRUE, as this will help</pre>

### Details

See compare\_motifs() for more info on comparison parameters.

If using a comparison metric where 0s are not allowed (KL, ALLR, ALLR\_LL, IS), then pseudocounts will be added internally. These pseudocounts are only used for comparison and alignment, and are not used in the final merging step.

Note: score.strat = "a.mean" is NOT recommended, as merge\_motifs() will not discriminate between two alignments with equal mean scores, even if one alignment is longer than the other.

### Value

A single motif object. See convert\_motifs() for available formats.

### Author(s)

m2 <- create_motif("AACC", name = "2")
m3 <- create_motif("AACCCGG", name = "3")
view_motifs(merge_motifs(c(m1, m2, m3)))
```

merge\_similar Identify and merge similar motifs within a collection of motifs.

### Description

Given a list of motifs, merge\_similar() will identify similar motifs with compare\_motifs(), and merge similar ones with merge\_motifs().

# Usage

```
merge_similar(motifs, threshold = 0.95, threshold.type = "score.abs",
  method = "PCC", use.type = "PPM", min.overlap = 6, min.mean.ic = 0,
  tryRC = TRUE, relative_entropy = FALSE, normalise.scores = FALSE,
  min.position.ic = 0, score.strat.compare = "a.mean",
  score.strat.merge = "sum", nthreads = 1)
```

34

# merge\_similar

motifs	See convert_motifs() for acceptable motif formats.
threshold	numeric(1) The minimum (for similarity metrics) or maximum (for distance metrics) threshold score for merging.
threshold type	character(1) Type of score used for thresholding. Currently unused.
method	character(1) One of PCC, EUCL, SW, KL, BHAT, HELL, SEUCL, MAN, WEUCL, WPCC. See compare_motifs(). (The ALLR and ALLR_LL methods cannot be used for distance matrix construction.)
use.type	character(1) One of 'PPM' and 'ICM'. The latter allows for taking into ac- count the background frequencies if relative_entropy = TRUE. Note that 'ICM' is not allowed when method = c("ALLR", "ALLR_LL").
min.overlap	numeric(1) Minimum overlap required when aligning the motifs. Setting this to a number higher then the width of the motifs will not allow any overhangs. Can also be a number between 0 and 1, representing the minimum fraction that the motifs must overlap.
min.mean.ic	<pre>numeric(1) Minimum mean information content between the two motifs for an alignment to be scored. This helps prevent scoring alignments between low information content regions of two motifs. Note that this can result in some comparisons failing if no alignment passes the mean IC threshold. Use average_ic() to filter out low IC motifs to get around this if you want to avoid getting NAs in your output.</pre>
tryRC	logical(1) Try the reverse complement of the motifs as well, report the best score.
relative_entrop	
	<pre>logical(1) Change the ICM calculation affecting min.position.ic and min.mean.ic. See convert_type().</pre>
normalise.score	2S
	logical(1) Favour alignments which leave fewer unaligned positions, as well as alignments between motifs of similar length. Similarity scores are multiplied by the ratio of aligned positions to the total number of positions in the larger motif, and the inverse for distance scores.
<pre>min.position.ic</pre>	
	numeric(1) Minimum information content required between individual align- ment positions for it to be counted in the final alignment score. It is recom- mended to use this together with normalise.scores = TRUE, as this will help punish scores resulting from only a fraction of an alignment.
score.strat.compare	
	character(1) The score.strat parameter used by compare_motifs(). For clustering purposes, the "sum" option cannot be used.
<pre>score.strat.mer</pre>	-
	<pre>character(1) The score.strat parameter used by merge_motifs(). As dis- cussed in merge_motifs(), the "sum" option is recommended over "a.mean" to maximize the overlap between motifs.</pre>
nthreads	<pre>numeric(1) Run compare_motifs() in parallel with nthreads threads. nthreads = 0 uses all available threads.</pre>

# Details

See compare\_motifs() for more info on comparison parameters, and merge\_motifs() for more info on motif merging.

### Value

See convert\_motifs() for available output formats.

motifs <- merge_similar(motifs)
length(motifs)
```

## End(Not run)

motif\_peaks

Look for overrepresented motif position peaks in a set of sequences.

# Description

Using the motif position data from scan\_sequences() (or elsewhere), test whether certain positions in the sequences have significantly higher motif density.

### Usage

```
motif_peaks(hits, seq.length, seq.count, bandwidth, max.p = 1e-06,
    peak.width = 3, nrand = 100, plot = TRUE, BP = FALSE)
```

hits	numeric A vector of sequence positions indicating motif sites.
seq.length	numeric(1) Length of sequences. Only one number is allowed, as all sequences must be of identical length. If missing, then the largest number from hits is used.

seq.count	numeric(1) Number of sequences with motif sites. If missing, then the number of unique values in hits is used.
bandwidth	numeric(1) Peak smoothing parameter. Smaller numbers will result in skinnier peaks, larger numbers will result in wider peaks. Leaving this empty will cause motif_peaks() to generate one by itself (see 'details').
max.p	numeric(1) Maximum P-value allowed for finding significant motif site peaks.
peak.width	<code>numeric(1)</code> Minimum peak width. A peak is defined as as the highest point within the value set by peak.width.
nrand	numeric(1) Number of random permutations for generating a null distribution. In order to calculate P-values, a set of random motif site positions are generated nrand times.
plot	logical(1) Will create a ggplot2 object displaying motif peaks.
BP	<pre>logical(1) Allows for the use of BiocParallel within motif_peaks(). See BiocParallel::register() to change the default backend. Setting BP = TRUE is only recommended for exceptionally large jobs. Keep in mind that this func- tion will not attempt to limit its memory usage.</pre>

# Details

Kernel smoothing is used to calculate motif position density. The implementation for this process is based on code from the **KernSmooth** R package (Wand 2015). These density estimates are used to determine peak locations and heights. To calculate the P-values of these peaks, a null distribution is calculated from peak heights of randomly generated motif positions.

If the bandwidth option is not supplied, then the following code is used (from KernSmooth):

del0 <-(1 / (4 \* pi))^(1 / 10)

bandwidth <-del0 \* (243 / (35 \* length(hits)))^(1 / 5) \* sqrt(var(hits))</pre>

## Value

A DataFrame with peak positions and P-values. If plot = TRUE, then a list is returned with the DataFrame as the first item and the ggplot2 object as the second item.

motif\_pvalue

#### *Motif P-value and scoring utility*

# Description

For calculating P-values and logodds scores from P-values for any number of motifs.

## Usage

```
motif_pvalue(motifs, score, pvalue, bkg.probs, use.freq = 1, k = 8,
    nthreads = 1, rand.tries = 10, rng.seed = sample.int(10000, 1),
    allow.nonfinite = FALSE, method = c("dynamic", "exhaustive"))
```

## Arguments

motifs	See convert_motifs() for acceptable motif formats.
score	numeric, list Get a P-value for a motif from a logodds score. See details for an explanation of how to vectorize the calculation for method = "dynamic".
pvalue	numeric, list Get a logodds score for a motif from a P-value. See details for an explanation of how to vectorize the calculation for method = "dynamic".
bkg.probs	<pre>numeric, list A vector background probabilities. If supplying individual back- ground probabilities for each motif, a list of such vectors. If missing, retrieves the background from the motif bkg slot. Note that this option is only used when method = "dynamic", or when method = "exhaustive" and providing a P-value and returning a score; for the inverse, the motifs are first converted to PWMs via convert_type(), which uses the motif bkg slot for background ad- justment.</pre>
use.freq	numeric(1) By default uses the regular motif matrix; otherwise uses the corresponding multifreq matrix. Max is 3 when method = "exhaustive".

38

<ul> <li>k numeric(1) For speed, scores/P-values can be approximated after subsetting the motif every k columns when method = "exhaustive". If k is a value equal or higher to the size of input motif(s), then the calculations are exact. The default, 8, is recommended to those looking for a good tradeoff between speed and accuracy for jobs requiring repeated calculations. Note that this is ignored when method = "dynamic", as subsetting is not required.</li> <li>nthreads numeric(1) Run motif_pvalue() in parallel with nthreads threads. nthreads = 0 uses all available threads. Currently only applied when method = "exhaustive".</li> <li>rand.tries numeric(1) When ncol(motif) &lt; k and method = "exhaustive", an approximation is used. This involves randomly approximating the overall motif score distribution. To increase accuracy, the distribution is approximated rand.tries times and the final scores averaged. Note that this is ignored when method = "dynamic", as subsetting is not required.</li> <li>rng. seed numeric(1) In order to allow motif_pvalue() to perform C++ level parallelisation, it must work independently from R. This means it cannot communicate with R to get/set the R RNG state. To get around this, the RNG seed used by the C++ function can be set with rng.seed. To make sure each thread gets a different seed however, the seed is multiplied with the iteration court. For example: when working with two motifs, the second motif gets the following seed: rng.seed * 2. The default is to pick a random number as chosen by sample(), which effectively makes motif_pvalue() dependent on the R RNG state. Note that this is ignored when method = "exhaustive".</li> <li>allow.nonfinite</li> <li>logical(1) If FALSE, then apply a pseudocount if non-finite values are found in the PWM. Note that if the motif has a pseudocount is applied. To disable this, set options(pseudocount.warning=FALSE).</li> <li>method character(1) One of c("dynamic", "exhaustive"). # Details

# **Regarding vectorization:**

A note regarding vectorizing the calculation when method = "dynamic" (no vectorization is possible with method = "exhaustive"): to avoid performing the P-value/score calculation repeatedly for individual motifs, provide the score/pvalue arguments as a list, with each entry corresponding to the scores/P-values to be calculated for the respective motifs provided to motifs. If you simply provide a list of repeating motifs and a single numeric vector of corresponding input scores/P-values, then motif\_pvalue() will not vectorize. See the Examples section.

#### The dynamic method:

One of the algorithms available to motif\_pvalue() to calculate scores or P-values is the dynamic programming algorithm used by FIMO (Grant et al., 2011). In this method, a small range of possible scores from the possible miminum and maximum is created and the cumulative probability of each score in this distribution is incrementally calculated using the logodds scores and the background probabilities. This distribution of scores and associated P-values can be used to calculate P-values or scores for any input, any number of times. This method scales well with large motifs, and multifreq representations. The only downside is that it is incompatible with allow.nonfinite = TRUE, as this would not allow for the creation of the initial range of scores. Although described for a different purpose, the basic premise of the dynamic programming algorithm is also described in Gupta et al. (2007).

#### The exhaustive method:

Calculating P-values exhaustively for motifs can be very computationally intensive. This is due to how P-values must be calculated: for a given score, all possible sequences which score equal or higher must be found, and the probability for each of these sequences (based on background probabilities) summed. For a DNA motif of length 10, the number of possible unique sequences is  $4^{10} = 1,048,576$ . Finding all possible sequences higher than a given score can be done very efficiently and quickly with a branch-and-bound algorithm, but as the motif length increases even this calculation becomes impractical. To get around this, the P-value calculation can be approximated.

In order to calculate P-values for longer motifs, this function uses the approximation proposed by Hartmann et al. (2013), where the motif is subset, P-values calculated for the subsets, and finally combined for a total P-value. The smaller the size of the subsets, the faster the calculation; but also, the bigger the approximation. This can be controlled by setting k. In fact, for smaller motifs (< 13 positions) calculating exact P-values can be done individually in reasonable time by setting k = 12.

To calculate a score from a P-value, all possible scores are calculated and the (1 - pvalue) \* 100 nth percentile score returned. When k < ncol(motif), the complete set of scores is instead approximated by randomly adding up all possible scores from each subset. Note that this approximation can actually be potentially quite expensive at times and even slower than the exact version; for jobs requiring lots of repeat calculations, a bit of benchmarking beforehand can be useful to find the optimal settings.

Please note that bugs are more likely to occur when using the exhaustive method, as the algorithm contains several times more code compared to the dynamic method. Unless you have a strong need to use allow.nonfinite = TRUE then avoid using this method.

#### Value

numeric, list A vector or list of vectors of scores/P-values.

#### Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

#### motif\_pvalue

#### Examples

```
if (R.Version()$arch != "i386") {
```

```
## P-value/score calculations are performed using the PWM version of the
## motif
data(examplemotif)
## Get a minimum score based on a P-value
motif_pvalue(examplemotif, pvalue = 0.001)
## Get the probability of a particular sequence hit
motif_pvalue(examplemotif, score = 0)
## The calculations can be performed for multiple motifs
motif_pvalue(c(examplemotif, examplemotif), pvalue = c(0.001, 0.0001))
## Compare score thresholds and P-value:
scores <- motif_score(examplemotif, c(0.6, 0.7, 0.8, 0.9))</pre>
motif_pvalue(examplemotif, scores)
## Calculate the probability of getting a certain match or better:
TATATAT <- score_match(examplemotif, "TATATAT")</pre>
TATATAG <- score_match(examplemotif, "TATATAG")</pre>
motif_pvalue(examplemotif, TATATAT)
motif_pvalue(examplemotif, TATATAG)
## Get all possible matches by P-value:
get_matches(examplemotif, motif_pvalue(examplemotif, pvalue = 0.0001))
## Vectorize the calculation for multiple motifs and scores/P-values:
m <- create_motif()</pre>
motif_pvalue(c(examplemotif, m), list(1:5, 2:3))
## The non-vectorized equivalent:
motif_pvalue(
  c(rep(list(examplemotif), 5), rep(list(m), 2)), c(1:5, 2:3)
)
}
```

```
motif_rc
```

Get the reverse complement of a DNA or RNA motif.

# Description

For any motif, change the motif slot to it's reverse complement. If the multifreq slot is filled, then it is also applied. No other slots are affected.

## Usage

```
motif_rc(motifs, ignore.alphabet = FALSE)
```

# Arguments

notifs	See convert_	_motifs() for	r acceptable formats

ignore.alphabet

logical(1) If TRUE, then motif\_rc() throws an error when it detects a non-DNA/RNA motif. If FALSE, it will proceed regardless.

# Value

See convert\_motifs() for available output formats.

# Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

### Examples

motif\_tree

### Description

For more powerful motif tree functions, see the **motifStack** package. The motif\_tree() function compares motifs with compare\_motifs() to create a distance matrix, which is used to generate a phylogeny. This can be plotted with ggtree::ggtree(). The purpose of this function is simply to combine the compare\_motifs() and ggtree::ggtree() steps into one. For more control over tree creation, it is recommend to do these steps separately. See the "Motif comparisons and P-values" vignette for such a workthrough. This function requires the **ape** and **ggtree** packages to be installed separately.

#### Usage

```
motif_tree(motifs, layout = "circular", linecol = "family",
labels = "none", tipsize = "none", legend = TRUE,
branch.length = "none", db.scores, method = "EUCL", use.type = "PPM",
min.overlap = 6, min.position.ic = 0, tryRC = TRUE, min.mean.ic = 0,
relative_entropy = FALSE, progress = FALSE, nthreads = 1,
score.strat = "a.mean", ...)
```

## Arguments

motifs	list, dist See convert_motifs() for available formats. Alternatively, the resulting comparison matrix from compare_motifs() (run as.dist(results) beforehand; if the comparison was performed with a similarity metric, make sure to convert to distances first).
layout	<pre>character(1) One of c('rectangular','slanted','fan','circular','radial','equal_angle' See ggtree::ggtree().</pre>
linecol	character(1) universalmotif slot to use to colour lines (e.g. 'family'). Not available for dist input (see examples for how to add it manually). See ggtree::ggtree().
labels	character(1) universalmotif slot to use to label tips (e.g. 'name'). For dist input, only 'name' is available. See ggtree::ggtree().
tipsize	character(1) universalmotif slot to use to control tip size (e.g. 'icscore'). Not available for dist input (see examples for how to add it manually). See ggtree::ggtree().
legend	logical(1) Show legend for line colour and tip size. See ggtree::ggtree().
branch.length	character(1) If 'none', draw a cladogram. See ggtree::ggtree().
db.scores	<pre>data.frame See compare_motifs().</pre>
method	character(1) One of PCC, EUCL, SW, KL, ALLR, BHAT, HELL, SEUCL, MAN, ALLR_LL, WEUCL, WPCC. See details.
use.type	character(1)c('PPM', 'ICM'). The latter allows for taking into account the back- ground frequencies (only if relative_entropy = TRUE'). See compare_motifs().

min.overlap	numeric(1) Minimum overlap required when aligning the motifs. Setting this to a number higher then the width of the motifs will not allow any overhangs.	
	Can also be a number between 0 and 1, representing the minimum fraction that	
	the motifs must overlap.	
<pre>min.position.ic</pre>		
	numeric(1) Minimum information content required between individual align- ment positions for it to be counted in the final alignment score. It is recom- mended to use this together with normalise.scores = TRUE, as this will help punish scores resulting from only a fraction of an alignment.	
tryRC	logical(1) Try the reverse complement of the motifs as well, report the best score.	
min.mean.ic	numeric(1) Minimum mean information content between the two motifs for an alignment to be scored. This helps prevent scoring alignments between low information content regions of two motifs. Note that this can result in some comparisons failing if no alignment passes the mean IC threshold. Use average_ic() to filter out low IC motifs to get around this if you want to avoid getting NAs in your output.	
relative_entropy		
	$\label{eq:logical(1)} logical(1) Change the ICM calculation affecting min.position.ic and min.mean.ic. \\ See \ convert_type().$	
progress	logical(1) Show message regarding current step.	
nthreads	<pre>numeric(1) Run compare_motifs() in parallel with nthreads threads. nthreads = 0 uses all available threads.</pre>	
score.strat	character(1) How to handle column scores calculated from motif alignments. "sum": add up all scores. "a.mean": take the arithmetic mean. "g.mean": take the geometric mean. "median": take the median. "wa.mean", "wg.mean": weighted arithmetic/geometric mean. "fzt": Fisher Z-transform. Weights are the total information content shared between aligned columns.	
	ggtree params. See ggtree::ggtree().	

# Details

See compare\_motifs() for more info on comparison parameters.

# Value

ggplot object.

```

read\_cisbp

Import CIS-BP motifs.

#### Description

Import CIS-BP formatted motifs. See http://cisbp.ccbr.utoronto.ca/index.php. Assumed to be DNA motifs.

## Usage

read\_cisbp(file, skip = 0)

## Arguments

file	character(1) File name.
skip	numeric(1) If not zero, will skip however many desired lines in the file before starting to read.

## Details

CIS-BP motifs can be formatted with or without additional header metadata. Motifs without any header start at instances of the word "Pos", whereas motifs with a header start at instances of the word "TF".

# Value

list universalmotif objects.

# Examples

read\_matrix

# Description

Import simply formatted motifs.

## Usage

```
read_matrix(file, skip = 0, type, positions = "columns",
    alphabet = "DNA", sep = "", headers = TRUE, rownames = FALSE,
    comment = NULL)
```

# Arguments

file	character(1) File name.
skip	numeric(1) If not zero, will skip however many desired lines in the file before starting to read.
type	character(1) One of c('PCM', 'PPM', 'PWM', 'ICM'). If missing will try and guess which one.
positions	character(1) One of c('columns', 'rows'). Partial matching allowed. Indi- cate whether each position within a motif is represented as a row or a column in the file.
alphabet	character(1) One of c('DNA', 'RNA', 'AA'), or a string of letters.
sep	character(1) Indicates how individual motifs are separated. Set as NULL if there are no seperating lines between motifs (the default is to assume a blank line).
headers	logical(1), character(1) Indicating if and how to read names.
rownames	logical(1) Are there alphabet letters present as rownames?
comment	NULL, character(1) Character denoting lines to be considered comments.

# Value

list universalmotif objects.

# Author(s)

hocomoco <- read_matrix(hocomoco, headers = ">", positions = "rows")
```

read\_meme

#### Import MEME motifs.

## Description

Import MEME formatted motifs, as well as original motif sequences. See <a href="http://meme-suite.org/doc/meme-format.html">http://meme-suite.org/doc/meme-format.html</a>. Both 'full' and 'minimal' formats are supported. DREME and STREME motifs can also be imported, but note that readsites and readsites.meta arguments do nothing.

### Usage

```
read_meme(file, skip = 0, readsites = FALSE, readsites.meta = FALSE)
```

## Arguments

file	character(1) File name.
skip	numeric(1) If not zero, will skip however many desired lines in the file before starting to read.
readsites	logical(1) If TRUE, the motif sites will be read as well.
readsites.meta	<pre>logical(1) If readsites = TRUE, then additionally read site positions and P- values.</pre>

## Details

Please note that the typical number precision limit in R is around 1e-308. This means that motif P-values in MEME files below this limit are rounded automatically to 0. To get around this, the E-value is also stored as a string in the extrainfo slot. If you require a numeric value for analysis, use the log\_string\_pval() function to get the log of the string-formatted p-value.

#### Value

list universalmotif objects. If readsites = TRUE, a list comprising of a sub-list of motif objects and a sub-list of motif sites will be returned. If readsites.meta = TRUE, then two additional list items will be present, one containing site positions and P-values, and another containing combined sequence p-values.

"/memerun.log"), readsites = TRUE, echo = FALSE, verbose = 1,
timeout = Inf, bin = getOption("meme.bin"))
```

## Arguments

target.sequences	
	XStringSet List of sequences to get motifs from.
output	character(1) Name of the output folder. If NULL, MEME output will be deleted.
overwrite.dir	logical(1) If output is set but already exists, allow over-writing.
control.sequend	ces
	XStringSet List of negative sequences. Only used if objfun = c("de", "se").
weights	numeric Vector of numbers between 0 and 1, representing sequence weights.
text	logical(1) [MEME]
brief	numeric(1) [MEME]
objfun	character(1) [MEME]
test	character(1) [MEME]
use_llr	logical(1) [MEME]
shuf	numeric(1)[MEME]

# run\_meme

sample\_sites

Generate binding sites from a motif.

# Description

Given probabilities for a sequence as represented by a motif, generate random sequences with the same length as the motif.

#### scan\_sequences

## Usage

sample\_sites(motif, n = 100, use.freq = 1)

### Arguments

motif	See convert_motifs() for acceptable formats.
n	numeric(1) Number of sites to generate.
use.freq	numeric(1) If one, use regular motif matrix. Otherwise, use respective multifreq matrix.

### Value

XStringSet object.

## Author(s)

## See Also

create\_sequences(), create\_motif(), add\_multifreq()

#### Examples

```
motif <- create_motif()
sites <- sample_sites(motif)</pre>
```

scan\_sequences Scan sequences for matches to input motifs.

## Description

For sequences of any alphabet, scan them using the PWM matrices of a set of input motifs.

## Usage

```
scan_sequences(motifs, sequences, threshold = 1e-04,
threshold.type = c("pvalue", "qvalue", "logodds", "logodds.abs"),
RC = FALSE, use.freq = 1, verbose = 0, nthreads = 1,
motif_pvalue.k = 8, use.gaps = TRUE, allow.nonfinite = FALSE,
warn.NA = TRUE, calc.pvals = TRUE, return.granges = FALSE,
no.overlaps = FALSE, no.overlaps.by.strand = FALSE,
no.overlaps.strat = c("score", "order"), respect.strand = FALSE,
motif_pvalue.method = c("dynamic", "exhaustive"),
calc.qvals = calc.pvals, calc.qvals.method = c("fdr", "BH",
"bonferroni"))
```

# Arguments

motifs	See convert_motifs() for acceptable motif formats.
sequences	XStringSet Sequences to scan. Alphabet should match motif.
threshold	numeric(1) See details.
threshold.type	character(1) One of c('pvalue','qvalue','logodds','logodds.abs'). See details.
RC	logical(1) If TRUE, check reverse complement of the input sequences. Only available for DNA/RNA.
use.freq	numeric(1) The default, 1, uses the motif matrix (from the motif['motif'] slot) to search for sequences. If a higher number is used, then the matching k-let matrix from the motif['multifreq'] slot is used. See add_multifreq().
verbose	numeric(1) Describe progress, from none ( $\emptyset$ ) to verbose (3).
nthreads	<pre>numeric(1) Run scan_sequences() in parallel with nthreads threads. nthreads = 0 uses all available threads. Note that no speed up will occur for jobs with only a single motif and sequence.</pre>
motif_pvalue.k	<pre>numeric(1) Control motif_pvalue() approximation. See motif_pvalue(). Only used if motif_pvalue.method = "exhaustive".</pre>
use.gaps	logical(1) Set this to FALSE to ignore motif gaps, if present.
allow.nonfinite	
	logical(1) If FALSE, then apply a pseudocount if non-finite values are found in the PWM. Note that if the motif has a pseudocount greater than zero and the mo- tif is not currently of type PWM, then this parameter has no effect as the pseu- docount will be applied automatically when the motif is converted to a PWM internally. This value is set to FALSE by default in order to stay consistent with pre-version 1.8.0 behaviour. Also note that this parameter is not compatible with motif_pvalue.method = "dynamic". A message will be printed if a pseudo- count is applied. To disable this, set options(pseudocount.warning=FALSE).
warn.NA	logical(1) Whether to warn about the presence of non-standard letters in the input sequence, such as those in masked sequences.
calc.pvals	logical(1) Calculate P-values for each hit. This is a convenience option which simply gives motif_pvalue() the input motifs and the scores of each hit. Be careful about setting this to TRUE if you anticipate getting thousands of hits and are using motif_pvalue.method = "exhaustive": expect to wait a few sec- onds or minutes for the calculations to finish. Increasing the nthreads value can help greatly here. See Details for more information on P-value calculation. If motif_pvalue.method = "dynamic", then this is usually not an issue.
return.granges	logical(1) Return the results as a GRanges object. Requires the GenomicRanges package to be installed.
no.overlaps	logical(1) Remove overlapping hits from the same motifs. Overlapping hits from different motifs are preserved. Please note that the current implementation of this feature can add significantly to the run time for large inputs.
no.overlaps.by.strand	
	logical(1) Whether to discard overlapping hits from the opposite strand, or to only discard overlapping hits on the same strand.

no.overlaps.strat

character(1) One of c("score", "order"). The former option keeps the highest scoring overlapping hit (and the first of these within ties), and the latter simply keeps the first overlapping hit.

respect.strand logical(1) If motifs are DNA/RNA, then setting this option to TRUE will make scan\_sequences() only scan the strands of the input sequences as indicated in the motif strand slot.

motif\_pvalue.method

character(1) One of c("dynamic", "exhaustive"). Algorithm used for calculating P-values. The "exhaustive" method involves finding all possible motif matches at or above the specified score using a branch-and-bound algorithm, which can be computationally intensive (Hartman et al., 2013). Additionally, the computation must be repeated for each hit. The "dynamic" method calculates the distribution of possible motif scores using a much faster dynamic programming algorithm, and can be recycled for multiple scores (Grant et al., 2011). The only disadvantage is the inability to use allow.nonfinite = TRUE. See motif\_pvalue() for details.

calc.qvals logical(1) Whether to also calculate adjusted P-values. Only valid if calc.pvals = TRUE.

calc.qvals.method

character(1) One of c("fdr", "BH", "bonferroni"). The method for calculating adjusted P-values. These are described in depth in the Sequence Searches vignette. Also see Noble (2009).

## Details

## Logodds scoring:

Similar to Biostrings::matchPWM(), the scanning method uses logodds scoring. (To see the scoring matrix for any motif, simply run convert\_type(motif, "PWM"). For a multifreq scoring matrix: apply(motif["multifreq"][["2"]],2,ppm\_to\_pwm)). In order to score a sequence, at each position within a sequence of length equal to the length of the motif, the scores for each base are summed. If the score sum is above the desired threshold, it is kept.

### Thresholds:

If threshold.type = 'logodds', then the threshold value is multiplied by the maximum possible motif scores. To calculate the maximum possible scores a motif (of type PWM) manually, run motif\_score(motif,1). If threshold.type = 'pvalue', then threshold logodds scores are generated using motif\_pvalue(). Finally, if threshold.type = 'logodds.abs', then the exact values provided will be used as thresholds. Finally, if threshold.type = 'qvalue', then the threshold is calculated as if threshold.type = 'pvalue' and the final set of hits are filtered based on their calculated Q-value. (Note: this means that the thresh.score column will be incorrect!) This is done since most Q-values cannot be calculated prior to scanning. If you are running a very large job, it may be wise to use a P-value threshold followed by manually filtering by Q-value; this will avoid the scanning have to parse the larger number of hits from the internally-lowered threshold.

#### Non-standard letters:

Non-standard letters (such as "N", "+", "-", ".", etc in DNAString objects) will be safely ignored, resulting only in a warning and a very minor performance cost. This can used to scan masked

sequences. See Biostrings::mask() for masking sequences (generating MaskedXString objects), and Biostrings::injectHardMask() to recover masked XStringSet objects for use with scan\_sequences(). There is also a provided wrapper function which performs both steps: mask\_seqs().

## Value

DataFrame, GRanges with each row representing one hit. If the input sequences are DNAStringSet or RNAStringSet, then an additional column with the strand is included. Function args are stored in the metadata slot. If return.granges = TRUE then a GRanges object is returned.

# A warning regarding the presence of non-standard letters will be given,
# but can be safely ignored in this case.
}
```

sequence\_complexity Calculate sequence complexity.

## Description

Calculate sequence complexity using either the Wootton-Federhen, Trifonov, or DUST algorithms.

## Usage

```
sequence_complexity(seqs, window.size = 20,
  window.overlap = round(window.size/2), method = c("WoottonFederhen",
  "WoottonFederhenFast", "Trifonov", "TrifonovFast", "DUST"),
  trifonov.max.word.size = 7, nthreads = 1, return.granges = FALSE)
```

### Arguments

seqs	XStringSet Input sequences.
window.size	numeric Window size. If a number between 0 and 1 is provided, the value is calculated as the number multiplied by the sequence length.
window.overlap	numeric Overlap between windows. If a number between 0 and 1 is provided, the value is calculated as the number multiplied by the sequence length.
method	character(1) Choose one of the available methods for calculating sequence complexity. See details.
trifonov.max.w	ord.size
	numeric(1) The maximum word size within each window used to calculate complexity using method = c("Trifonov", "TrifonovFast"). In other words, the Trifonov method involves counting the number of possible different subwords in a window at different sizes up to the values provided by this option. It also involves calculating the product of ever increasing sequences of numbers and so in order to reduce the computations involed this can be limited to a specific maximum sub-word size.
nthreads	<pre>numeric(1) Run sequence_complexity() in parallel with nthreads threads. nthreads = 0 uses all available threads.</pre>
return.granges	logical(1) Return the results as a GRanges object. Requires the GenomicRanges package to be installed.

### Details

The Wootton-Federhen (Wootton and Federhen, 1993) and Trifonov (Trifonov, 1990) algorithms as well as their faster approximations are well described within Orlov and Potapov (2004). These algorithms score less complex sequences closer to 0, and more complex ones closer to 1. Please note that the 'fast' approximation versions of the two methods are not actually faster within sequence\_complexity(), and so speed should not be a major consideration when choosing which method to use within the universalmotif package. The DUST algorithm implementation is described in Morgulis et al. (2006). In this case, less complex sequences score higher, and more complex ones closer to 0.

Briefly, the Wootton-Federhen complexity score is a reflection of the numbers of each unique letter found in the window (e.g. for DNA, the more of all four letters can be found in the window the higher the score). An increasing Trifonov score is a relection of the numbers of increasingly larger k-mers (e.g. the count of possible 1-mers, 2-mers, 3-mers, ..., until trifonov.max.word.size). Finally, the DUST score approaches 0 as the count of unique 3-mers increases. (See the final section in the examples to see how different types of sequence compositions affect the methods.)

Please note that the authors of the different methods recommend various window sizes and complexity thresholds. The authors of DUST for example, suggest using a window size of 64 and a threshold of 2 for low complexity. Wootton and Federhen suggest a window size of 40, though show that 10 and 20 can be appropriate as well (for amino acid sequences). Keep in mind however that these algorithms were implemented at a time when computers were much slower; perhaps the authors would suggest different window sizes today. One thing to note is that the Wootton-Federhen algorithm has a hard limit due to the need to caculate the product from 1:window.size. This can end up calculating values which are greater than what a double can hold (e.g. try prod(1:500)). Its approximation does not suffer from this though, as it skips calculating the product.

In terms of speed, the Wootton-Federhen algorithms are fastest, with DUST being 1-3 times slower and the Trifonov algorithms being several times slower (though the exact amount depends on the max word size).

#### Value

DataFrame, GRanges with each row getting a complexity score for each window in each input sequence.

## Author(s)

sequence_complexity(test.seq, method = "Trifonov")
sequence_complexity(test.seq, method = "TrifonovFast")
sequence_complexity(test.seq, method = "DUST")
## You could also use this in conjuction with mask_ranges() to hide
## low complexity regions from scanning, de novo motif discovery, etc
if (requireNamespace("GenomicRanges", quiet = TRUE)) {
data(ArabidopsisPromoters)
# Calculate complexity in 20 bp windows, sliding every 1 bp
to.mask <- sequence_complexity(ArabidopsisPromoters, method = "DUST",</pre>
 window.size = 20, window.overlap = 19, return.granges = TRUE)
# Get the ranges with a complexity score greater than 3.5
to.mask <- to.mask[to.mask$complexity > 3.5]
# See what the low complexity regions look like
ArabidopsisPromoters[IRanges::reduce(to.mask)]
# Mask them with the default '-' character:
mask_ranges(ArabidopsisPromoters, to.mask)
}
## To demonstrate how the methods work, consider:
## (These examples use the calc_complexity() utility which utilizes
## the same algorithms and works on character vectors, but lacks
## the ability to use sliding windows.)
a <- "ACGT"
# For Wootton-Federhen, it can be easily shown it is only dependent
# on the counts of individual letters (though do note that the
# original paper discusses this method in the context of amino acid
calc_complexity("AAACCCGGGTTT", alph = a) # 0.7707
calc_complexity("AACCGGTTACGT", alph = a) # 0.7707
calc_complexity("ACGTACGTACGT", alph = a) # 0.7707
# As letters start to see drops in counts, the scores go down too:
calc_complexity("AAAACCCCGGGG", alph = a) # 0.6284
calc_complexity("AAAAAACCCCCC", alph = a) # 0.4105
calc_complexity("AAAAAAAAAACC", alph = a) # 0.2518
# Trifonov on the other hand is greatly affected by the number
# of higher order combinations:
calc_complexity("AAACCCGGGTTT", c = "Trifonov", alph = a) # 0.6364
calc_complexity("AACCGGTTACGT", c = "Trifonov", alph = a) # 0.7273
# This next one may seem surprising, but it indeed scores very low.
```

```
# This is because although it has many of each individual letter,
# the number of higher order letter combinations in fact is quite
# low due to this particular repeating pattern!
calc_complexity("ACGTACGTACGT", c = "Trifonov", alph = a) # 0.01231
# By extension, this means it scores sequences with fewer
# counts of individual letters lower too.
calc_complexity("AAAACCCCGGGG", c = "Trifonov", alph = a) # 0.2386
calc_complexity("AAAAAACCCCCC", c = "Trifonov", alph = a) # 0.0227
calc_complexity("AAAAAAAAAACC", c = "Trifonov", alph = a) # 0.0011
# As for DUST, it considers the number of 3-mers in the sequence.
# The higher the numbers of 3-mers, the lower the score.
# (0 = the max possible number of DNA 3-mers for the window size)
calc_complexity("AAACCCGGGTTT", c = "DUST", alph = a) # 0
calc_complexity("AACCGGTTACGT", c = "DUST", alph = a) # 0
calc_complexity("ACGTACGTACGT", c = "DUST", alph = a) # 0.8889
calc_complexity("AAAACCCCGGGG", c = "DUST", alph = a) # 0.333
calc_complexity("ACGACGACGACG", c = "DUST", alph = a) # 1.333
calc_complexity("AAAAAACCCCCCC", c = "DUST", alph = a) # 1.333
# Similarly to Trifonov, the next one also scores as less complex
# compared to the previous one:
calc_complexity("ACACACACACAC", c = "DUST", alph = a) # 2.222
calc_complexity("AAAAAAAAAACC", c = "DUST", alph = a) # 3.111
calc_complexity("AAAAAAAAAAAAC", c = "DUST", alph = a) # 4
calc_complexity("AAAAAAAAAAAAA", c = "DUST", alph = a) # 5
# Just to show once more why the seemingly more complex sequences
# such as "ACACACACACAC" score as less complex than "AAAAAACCCCCC"
# for the Trifonov and DUST methods:
count_klets("ACACACACACAC", k = 3) # Only 2 possible 3-mers
count_klets("AAAAAACCCCCCC", k = 3) # Now 4 possible 3-mers!
```

shuffle\_motifs Shuffle motifs by column.

#### Description

Given a set of motifs, shuffle the columns to create new motifs. Currently does not support keeping the 'multifreq' slot. Only the 'bkg', 'nsites', 'strand', and 'bkgsites' slots will be preserved. Uses the same shuffling methods as shuffle\_sequences(). When shuffling more than one motif, all motif columns are merged into a single pool and shuffled together, finally returning them as motifs of identical lengths as the input motifs. To instead shuffle motifs individually, call shuffle\_motifs() using lapply().

#### Usage

```
shuffle_motifs(motifs, k = 2, method = "linear")
```

64

# shuffle\_sequences

## Arguments

motifs	See convert_motifs() for acceptable formats.
k	numeric(1) K-let size.
method	character(1) Currently only 'linear' is accepted.

# Value

Motifs. See convert\_motifs() for available output formats.

# Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

## See Also

shuffle\_sequences()

shuffle\_sequences *Shuffle input sequences.* 

## Description

Given a set of input sequences, shuffle the letters within those sequences with any k-let size.

## Usage

```
shuffle_sequences(sequences, k = 1, method = "euler", nthreads = 1,
rng.seed = sample.int(10000, 1), window = FALSE, window.size = 0.1,
window.overlap = 0.01)
```

# Arguments

sequences	XStringSet Set of sequences to shuffle. Works with any set of characters.
k	numeric(1) K-let size.
method	<pre>character(1) One of c('euler', 'markov', 'linear'). Only relevant if k &gt; 1. See details.</pre>
nthreads	<pre>numeric(1) Run shuffle_sequences() in parallel with nthreads threads. nthreads = 0 uses all available threads. Note that no speed up will occur for jobs with only a single sequence.</pre>
rng.seed	<pre>numeric(1) Set random number generator seed. Since shuffling can occur si- multaneously in multiple threads using C++, it cannot communicate with the regular R random number generator state and thus requires an independent seed. Each individual sequence in an XStringSet object will be given the following seed: rng.seed * index. The default is to pick a random number as chosen by sample(), which effectively is making shuffle_sequences() dependent on the R RNG state.</pre>

window	logical(1) Shuffle sequences iteratively over windows instead of all at once.
window.size	numeric(1) Window size. Can be a fraction less than one, or an integer repre- senting the actual window size.
window.overlap	numeric(1) Overlap between windows. Can be a fraction less than one, or an integer representing the actual overlap size.

#### Details

### markov method:

If method = 'markov', then the Markov model is used to generate sequences which will maintain (on average) the k-let frequencies. Please note that this method is not a 'true' shuffling, and for short sequences (e.g. <100bp) this can result in slightly more dissimilar sequences versus true shuffling. See Fitch (1983) for a discussion on the topic.

#### euler method:

If method = 'euler', then the sequence shuffling method proposed by Altschul and Erickson (1985) is used. As opposed to the 'markov' method, this one preserves exact k-let frequencies. This is done by creating a k-let edge graph, then following a random Eulerian walk through the graph. Not all walks will use up all available letters however, so the cycle-popping algorithm proposed by Propp and Wilson (1998) is used to find a random Eulerian path. A side effect of using this method is that the starting and ending sequence letters will remain unshuffled.

#### linear method:

If method = 'linear', then the input sequences are split linearly every k letters. For example, for k = 3 'ACAGATAGACCC' becomes 'ACA GAT AGA CCC'; after which these 3-lets are shuffled randomly.

## Single-letter shuffling:

Do note however, that the method parameter is only relevant for k > 1. For k = 1, a simple shuffling is performed using the shuffle function from the C++ standard library.

## Value

XStringSet The input sequences will be returned with identical names and lengths.

create\_motif()

## Examples

```
DNA.motif <- create_motif()
RNA.motif <- switch_alph(DNA.motif)</pre>
```

tidy-motifs

# Description

Tidy manipulation of motifs.

## Usage

```
to_df(motifs, extrainfo = TRUE)
update_motifs(motif_df, extrainfo = TRUE, force = FALSE)
to_list(motif_df, extrainfo = TRUE, force = FALSE)
requires_update(motifs, extrainfo = TRUE)
```

# Arguments

motifs	List of motifs.
extrainfo	Use the extrainfo slot in the tidy data.frame. The column names will be taken from the character vectors themselves, and unnamed elements will be assigned a unique name. To add elements to the slot, simply create new columns in the data.frame. Note that these will be coerced into characters. If extrainfo is not set to TRUE in to_df(), then the contents of the slot will not be transferred to the data.frame. If extrainfo is not set to TRUE in update_motifs() or to_list(), then the extra columns will be discarded.
motif_df	Motif data.frame generated by to_df().
force	Whether to coerce non-character data types into characters for inclusion in extrainfo. If force is FALSE (the default), columns which are not of type "character", "numeric", or "integer" (for example, list columns, or logical values), will not be added to the motif extrainfo slot, but will be passed onto the returned universalmotif_df unchanged. Setting force = TRUE coerces these values into a character, adding them to the extrainfo slot, and updating the universalmotif_df columns to reflect this coercion. In other words, forcing inclusion of these data is destructive and will change the column values. Use with caution.

# Details

To turn off the informative messages/warnings when printing the object to the console, set options(universalmotif\_df.wa

# Value

For to\_df(): a data.frame with the exposed slots as columns.
For update\_motifs(): the updated data.frame.

# trim\_motifs

For requires\_update(): TRUE if the motifs are out of date, FALSE if otherwise. Note that this function uses identical() to check for this, which can be quite slow for large datasets. It is usually just as fast to simply run update\_motifs() in such cases.

For to\_list(): a list of motifs.

## Author(s)

## Examples

```
## Not run:
library(universalmotif)
library(dplyr)
m <- c(create_motif(name = "motif A"), create_motif(name = "motif B"))
# Change the names of the motifs using the tidy way:
m <- m %>%
    to_df() %>%
    mutate(name = paste0(name, "-2")) %>%
    to_list()
# Add your own metadata to be stored in the extrainfo slot:
m_df <- to_df(m)
m_df$MyMetadata <- c("Info_1", "Info_2")
m <- to_list(m_df, extrainfo = TRUE)
## End(Not run)
```

trim\_motifs Trim motifs.

## Description

Remove edges of motifs with low information content. Currently does not trim multifreq representations.

## Usage

```
trim_motifs(motifs, min.ic = 0.25, trim.from = c("both", "left", "right"))
```

# Arguments

motifs	See convert_motifs() for acceptable formats.
min.ic	<pre>numeric(1) Minimum allowed information content. See convert_type() for a discussion on information content.</pre>
trim.from	character(1) Control the direction of trimming.

# Value

Motifs See convert\_motifs() for available output formats.

```

## Arguments

universalmotif Motif. х i character Slot. Object to replace slot with. value universalmotif Final motif. .Object character(1) Motif name. name altname character(1) Alternate motif name. family character(1) Transcription factor family. organism character(1) Species of origin. motif matrix Each column represents a position in the motif. alphabet character(1) One of c('DNA', 'RNA', 'AA'), or a combined string representing the letters. character(1) One of c('PCM', 'PPM', 'PWM', 'ICM'). type

icscore	numeric(1) Total information content. Automatically generated.
nsites	numeric(1) Number of sites the motif was constructed from.
pseudocount	numeric(1) Correction to be applied to prevent -Inf from appearing in PWM matrices.
bkg	numeric A vector of probabilities, each between 0 and 1. If higher order back- grounds are provided, then the elements of the vector must be named.
bkgsites	numeric(1) Total number of sites used to find the motif.
consensus	character(1) Consensus string. Automatically generated for 'DNA', 'RNA', and 'AA' alphabets.
strand	character(1) Whether the motif is specific to a certain strand.
pval	numeric(1) P-value associated with motif.
qval	numeric(1) Adjusted P-value associated with motif.
eval	numeric(1) E-value associated with motif.
multifreq	<pre>list See add_multifreq().</pre>
extrainfo	character Any other extra information, represented as a named character vec- tor.
gapinfo	universalmotif_gapped(1) Gapped motif information.
object	universalmotif Motif.
select	numeric Columns to keep.
	universalmotif Motifs.
deparse.level	Unused.

## Value

A motif object of class universalmotif.

# Slots

```
name character(1)
altname character(1)
family character(1)
organism character(1)
motif matrix
alphabet character(1)
type character(1)
icscore numeric(1) Generated automatically.
nsites numeric(1)
pseudocount numeric(1)
bkg numeric 0-order probabilities must be provided for all letters.
bkgsites numeric(1)
```

consensus character Generated automatically.
strand character(1)
pval numeric(1)
qval numeric(1)
eval numeric(1)
multifreq list
extrainfo character
gapinfo universalmotif\_gapped(1)

# Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

## Examples

```
## [
## Access the slots.
motif <- create_motif()</pre>
motif["motif"]
# you can also access multiple slots at once, released as a list
motif[c("motif", "name")]
## [<-
## Replace the slots.
motif["name"] <- "new name"</pre>
# some slots are protected
# motif["consensus"] <- "AAAA" # not allowed</pre>
## c
## Assemble a list of motifs.
c(motif, motif)
## as.data.frame
## Represent a motif as a data.frame. The actual motif matrix is lost.
## Necessary for `summarise_motifs`.
as.data.frame(motif)
## subset
## Subset a motif matrix by column.
subset(motif, 3:7) # extract motif core
## normalize
## Apply the pseudocount slot (or `1`, if the slot is set to zero) to the
## motif matrix.
motif2 <- create_motif("AAAAA", nsites = 100, pseudocount = 1)</pre>
normalize(motif2)
## rowMeans
## Calculate motif rowMeans.
rowMeans(motif)
```

## colMeans ## Calculate motif colMeans. colMeans(motif) ## colSums ## Calculate motif colSums colSums(motif) ## rowSums ## Calculate motif rowSums. rowSums(motif) ## nrow ## Count motif rows. nrow(motif) ## ncol ## Count motif columns. ncol(motif) ## colnames ## Get motif colnames. colnames(motif) ## rownames ## Get motif rownames. rownames(motif) ## cbind ## Bind motifs together to create a new motif. cbind(motif, motif2)

universalmotif-pkg universalmotif: Import, Modify and Export Motifs with R

## Description

A collection of utility functions for working with motifs.

utilities

Utility functions.

## Description

Utility functions have been split into two categories: those related to motifs ?'utils-motif', and those related to sequences ?'utils-sequence'.

## utils-motif

#### Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

## See Also

utils-motif, utils-sequence

utils-motif

Motif-related utility functions.

#### Description

Motif-related utility functions.

## Usage

```
add_gap(motif, gaploc = ncol(motif)%/%2, mingap = 1, maxgap = 5)
average_ic(motifs, average = c("a.mean", "g.mean", "median", "fzt"))

score_match(motif, match, allow.nonfinite = FALSE)
summarise_motifs(motifs, na.rm = TRUE)
ungap(motif, delete = FALSE)
```

## Arguments

motif	Motif object to calculate scores from, or add/remove gap, or round.
gaploc	numeric Motif gap locations. The gap occurs immediately after every position value. If missing, uses round(ncol(motif) / 2).
mingap	numeric Minimum gap size. Must have one value for every location. If missing, set to 1.
maxgap	numeric Maximum gap size. Must have one value for every location. If missing, set to 5.
motifs	list A list of universalmotif motifs.
average	character(1) One of c("a.mean", "g.mean", "median", "fzt"). How to cal- culate the average motif information content.
х	numeric First column for comparison.
У	numeric Second column for comparison.
method	character(1) Column comparison metric. See compare_motifs() for details.
bkg1	numeric Vector of background probabilities for the first column. Only relevant if method = "ALLR".
bkg2	numeric Vector of background probabilities for the second column. Only relevant if method = "ALLR".
nsites1	<pre>numeric(1) Number of sites for the first column. Only relevant if method = "ALLR".</pre>

nsites2	numeric(1) Number of sites for the second column. Only relevant if method = "ALLR".
letter	character(1) Any DNA, RNA, or AA IUPAC letter. Ambiguity letters are accepted.
position	numeric A numeric vector representing the frequency or probability for each alphabet letter at a specific position.
alphabet	character(1) One of c('DNA', 'RNA').
type	character(1) One of c('PCM', 'PPM', 'PWM' 'ICM').
pseudocount	numeric(1) Used to prevent zeroes in motif matrix.
score	numeric(1) Logodds motif score.
allow.nonfinite	-
	logical(1) If FALSE, then apply a pseudocount if non-finite values are found in the PWM. Note that if the motif has a pseudocount greater than zero and the motif is not currently of type PWM, then this parameter has no effect as the pseudocount will be applied automatically when the motif is converted to a PWM internally. This value is set to FALSE by default in order to stay consistent with pre-version 1.8.0 behaviour. A message will be printed if a pseudocount is applied. To disable this, set options(pseudocount.warning=FALSE).
use.freq	numeric(1) Use regular motif or the respective multifreq representation.
threshold	numeric(1) Any number of numeric values between 0 and 1 representing score percentage.
threshold.type	character For "total", a threshold of zero represents the minimum possible score. This means the range of scores that can be extracted is from the minimum to the maximum possible scores. For "fromzero", a threshold of zero is a score of zero. This means the range of scores is from zero to the maximum. The "total" threshold type can only be used if no non-finite values are present in the PWM.
pval	character(1) String-formatted p-value.
bkg	numeric Should be the same length as the alphabet length.
nsites	numeric(1) Number of sites motif originated from.
relative_entrop	
	logical(1) Calculate information content as relative entropy or Kullback-Leibler divergence.
schneider_corre	
	logical(1) Apply sample size correction.
smooth	logical(1) Apply pseudocount correction.
match	character Sequence string to calculate score from.
allow.zero	logical(1) If FALSE, apply a pseudocount if zero values are found in the back- ground frequencies.
pct.tolerance	numeric(1) or character(1) The minimum tolerated proportion each letter must represent per position in order not to be rounded off, either as a numeric value from 0 to 1 or a percentage written as a string from " $0\%$ " to " $100\%$ ".
na.rm	logical Remove columns where all values are NA.
delete	logical(1) Clear gap information from motif. If FALSE, then it can be reactivated simply with add_gap(motif).

78

For consensus\_to\_ppm() and consensus\_to\_ppmAA(): a numeric vector of length 4 and 20, respectively.

For get\_consensus() and get\_consensusAA(): a character vector of length 1.

For get\_matches(): a character vector of motif matches.

For motif\_range(): a named numeric vector of motif scores.

For motif\_score(): a named numeric vector of motif scores.

For log\_string\_pval(): a numeric vector of length 1.

For position\_icscore(): a numeric vector of length 1.

For ppm\_to\_icm(), icm\_to\_ppm(), pcm\_to\_ppm(), ppm\_to\_pcm(), ppm\_to\_pwm(), and pwm\_to\_ppm(): a numeric vector with length equal to input numeric vector.

For prob\_match(): a numeric vector of probabilities.

For round\_motif(): the input motif, rounded.

For score\_match(): a numeric vector with the match motif score.

For summarise\_motifs(): a data.frame with columns representing the universalmotif slots.

utils-sequence

Sequence-related utility functions.

## Description

Sequence-related utility functions.

# Usage

```
calc_complexity(string, complexity.method = c("WoottonFederhen",
  "WoottonFederhenFast", "Trifonov", "TrifonovFast", "DUST"), alph = NULL,
  trifonov.max.word.size = 7)
calc_windows(n, window = 1, overlap = 0, return.incomp = TRUE)
count_klets(string, k = 1, alph)
get_klets(lets, k = 1)
mask_ranges(seqs, ranges, letter = "-")
mask_seqs(seqs, pattern, RC = FALSE, letter = "-")
shuffle_string(string, k = 1, method = c("euler", "linear", "markov"),
  rng.seed = sample.int(10000, 1))
slide_fun(string, FUN, FUN.VALUE, window = 1, overlap = 0,
  return.incomp = TRUE)
window_string(string, window = 1, overlap = 0, return.incomp = TRUE,
  nthreads = 1)
```

## Arguments

string	character(1) A character vector containing a single string, with the exception of calc_complexity() where string can be a length greater than one.	
complexity.met	hod	
	character(1) Complexity algorithm. See <pre>sequence_complexity().</pre>	
alph	character(1) A single character string with the desired sequence alphabet. If missing, finds the unique letters within each string.	
trifonov.max.word.size		
	<pre>integer(1) Maximum word size for use in the Trifonov complexity methods. See sequence_complexity().</pre>	
n	integer(1) Total size from which to calculate sliding windows.	
window	integer(1) Window size to slide along.	
overlap	integer(1) Overlap size between windows.	
return.incomp	logical(1) Whether to return the last window if it is smaller then the requested window size.	
k	integer(1) K-let size.	

# utils-sequence

lets	character A character vector where each element will be considered a single unit.
seqs	XStringSet Sequences to mask. Cannot be BStringSet.
ranges	GRanges The ranges to mask. Must be a GRanges object from the GenomicRanges package.
letter	character(1) Character to use for masking.
pattern	character(1) Pattern to mask.
RC	logical(1) Whether to mask the reverse complement of the pattern.
method	<pre>character(1) Shuffling method. One of c("euler","linear","markov"). See shuffle_sequences().</pre>
rng.seed	<pre>numeric(1) Set random number generator seed. Since shuffling in shuffle_sequences() can occur simultaneously in multiple threads using C++, it cannot communi- cate with the regular R random number generator state and thus requires an in- dependent seed. Since shuffle_string() uses the same underlying code as shuffle_sequences(), it also requires a separate seed even if it is run in serial.</pre>
FUN	closure The function to apply per window. (See ?vapply.)
FUN.VALUE	The expected return type for FUN. (See ?vapply.)
nthreads	integer(1) Number of threads to use. Zero uses all available threads.

## Value

For calc\_complexity(): A vector of numeric values.
For calc\_windows(): A data.frame with columns start and stop.
For count\_klets(): A data.frame with columns lets and counts.
For get\_klets(): A character vector of k-lets.
For mask\_ranges(): The masked XStringSet object.
For mask\_seqs(): The masked XStringSet object.
For shuffle\_string(): A single character string.
For slide\_fun(): A vector with type FUN.VALUE.
For window\_string(): A character vector.

*****
## slide_fun
```

view\_logo

Plot logos from numeric matrices.

## Description

This function provides the plotting capabilities of view\_motifs() without requiring universalmotifclass objects. Instead, it takes a numeric matrix with row names as input. Additionally, columns can be of any height and letters can be a mix of different character lengths.

## Usage

```
view_logo(x, fontDF = NULL, fill = "black", colour.scheme = NULL,
min.height = 0.01, x.spacer = 0.04, y.spacer = 0.01,
sort.positions = FALSE, sort.positions.decreasing = TRUE,
fit.to.height = NULL)
```

## Arguments

х	A numeric matrix with row names. The row names can be a mix of different character lengths.
fontDF	data.frame or DataFrame Polygon data for letters used for plotting, as gen- erated by the createPolygons() function from the gglogo package. See the fontDFroboto data object (which is used by default when fontDF = NULL). See Examples for how to generate your own font set. Expected columns: x, y, order, group; additional columns will be ignored.
fill	character A single colour to fill all letters with. Ignored if colour.scheme is provided.
colour.scheme	character A named character vector of colour names. Provide colours for individual letters, even if the row names are made up of multiple characters.
min.height	numeric(1) Minimum height for a letter to be plotted. The number is taken as the fraction of the total height of the plot. The default value is to not show letters which take up $1\%$ or less of the vertical space. For smaller figures it is recommended to increase this value, and vice versa for larger figures.

x.spacer	numeric(1) Add horizontal spacing between letters. The number is taken as the fraction of the width of an individual position. Increasing this value is recommended for letters made up of multiple characters.	
y.spacer	numeric(1) Add vertical spacing between letters. The number is taken as the fraction nof the total height of the plot.	
sort.positions	logical(1) Sort letters vertically per position by height.	
sort.positions.decreasing logical(1) Sort in decreasing or increasing order based on letter height.		
fit.to.height	<pre>numeric(1) Normalize the per position height to this value. If NULL, no normal- ization is applied. Note that this parameter is ignored if use.type = c("PWM", "ICM").</pre>	

# Value

A ggplot object. If you wish to plot the data yourself from polygon paths, access them using \$data on the output object. The theme\_void() is applied to the object; apply your own theme or adjust specific plot parameters with theme() to change this.

## Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

## See Also

view\_motifs()

# Examples

```
## Feel free to mix and match row name character lengths and column sums.
data(examplemotif)
toplot <- examplemotif["motif"]</pre>
toplot[4] <- 2
toplot[20] <- -0.5
rownames(toplot)[1] <- "AA"</pre>
view_logo(toplot)
```

view\_motifs

Plot motif logos.

## Description

Show sequence logo. If given a list of more than one motif, then the motifs are aligned with the first in the list.

# view\_motifs

### Usage

```
view_motifs(motifs, use.type = "ICM", method = "ALLR", tryRC = TRUE,
min.overlap = 6, min.mean.ic = 0.25, relative_entropy = FALSE,
normalise.scores = FALSE, min.position.ic = 0, score.strat = "sum",
return.raw = FALSE, dedup.names = TRUE, show.positions = TRUE,
show.positions.once = TRUE, show.names = TRUE, names.pos = c("top",
"right"), use.freq = 1, colour.scheme = NULL, fontDF = NULL,
min.height = 0.01, x.spacer = if (use.freq == 1) 0.04 else 0.1,
y.spacer = 0.01, sort.positions = !use.type %in% c("PCM", "PPM"),
sort.positions.decreasing = TRUE, text.size = 16, fit.to.height = if
(use.type == "PPM") 1 else NULL, RC.text = " [RC]", ...)
```

## Arguments

motifs	See convert_motifs() for acceptable motif formats.	
use.type	character(1) One of c('PCM','PPM','PWM','ICM').	
method	character(1) One of PCC, EUCL, SW, KL, ALLR, BHAT, HELL, SEUCL, MAN, ALLR_LL, WEUCL, WPCC. See details.	
tryRC	logical(1) Try the reverse complement of the motifs as well, report the best score.	
min.overlap	numeric(1) Minimum overlap required when aligning the motifs. Setting this to a number higher then the width of the motifs will not allow any overhangs. Can also be a number between 0 and 1, representing the minimum fraction that the motifs must overlap.	
min.mean.ic	<pre>numeric(1) Minimum mean information content between the two motifs for an alignment to be scored. This helps prevent scoring alignments between low information content regions of two motifs. Note that this can result in some comparisons failing if no alignment passes the mean IC threshold. Use average_ic() to filter out low IC motifs to get around this if you want to avoid getting NAs in your output.</pre>	
relative_entropy		
	<pre>logical(1) Change the ICM calculation affecting min.position.ic and min.mean.ic. See convert_type().</pre>	
normalise.score	25	
	logical(1) Favour alignments which leave fewer unaligned positions, as well as alignments between motifs of similar length. Similarity scores are multiplied by the ratio of aligned positions to the total number of positions in the larger motif, and the inverse for distance scores.	
min.position.ic		
	numeric(1) Minimum information content required between individual align- ment positions for it to be counted in the final alignment score. It is recom- mended to use this together with normalise.scores = TRUE, as this will help punish scores resulting from only a fraction of an alignment.	
score.strat	character(1) How to handle column scores calculated from motif alignments. "sum": add up all scores. "a.mean": take the arithmetic mean. "g.mean": take the geometric mean. "median": take the median. "wa.mean", "wg.mean":	

	weighted arithmetic/geometric mean. "fzt": Fisher Z-transform. Weights are the total information content shared between aligned columns.
return.raw	logical(1) Instead of returning a plot, return the aligned named matrices used to generate the plot. This can be useful if you wish to use view_motifs() align- ment capabilities for custom plotting uses. Alignment is performed by adding empty columns to the left or right of motifs to generate matrices of equal length.
dedup.names	logical(1) Plotting motifs with duplicated names is not allowed. Setting this to TRUE allows the names to be modified for plotting.
show.positions	logical(1) Show x-axis position tick labels.
show.positions	
	logical(1) When plotting multiple motifs, show x-axis position tick labels only once. If FALSE, then x-axis tick labels are specific to each motif.
show.names	logical(1) Add motif names when plotting multiple motifs.
names.pos	character(1) Motif name locations. Either above (top) or to the right (right) of the logos.
use.freq	numeric(1) Plot higher order motifs from the multifreq slot.
colour.scheme	character A named character vector of colour names. Default colours are pro- vided for DNA, RNA, and AA motifs if left NULL.
fontDF	data.frame or DataFrame Polygon data for letters used for plotting, as gen- erated by the createPolygons() function from the gglogo package. See the fontDFroboto data object (which is used by default when fontDF = NULL). See Examples for how to generate your own font set. Expected columns: x, y, order, group; additional columns will be ignored.
min.height	numeric(1) Minimum height for a letter to be plotted. The number is taken as the fraction of the total height of the plot. The default value is to not show letters which take up 1% or less of the vertical space. For smaller figures it is recommended to increase this value, and vice versa for larger figures.
x.spacer	numeric(1) Add horizontal spacing between letters. The number is taken as the fraction of the width of an individual position. Increasing this value is recommended for plotting multifreq motifs.
y.spacer	numeric(1) Add vertical spacing between letters. The number is taken as the fraction nof the total height of the plot.
sort.positions	logical(1) Sort letters vertically per position by height.
sort.positions.	
	logical(1) Sort in decreasing or increasing order based on letter height.
text.size	numeric(1) Text size for labels.
fit.to.height	numeric(1) Normalize the per position height to this value. If NULL, no normal- ization is applied. Note that this parameter is ignored if use.type = c("PWM", "ICM").
RC.text	character(1) The text to display alongside the name of motifs shown as their reverse complement.
	Unused. Was previously in place to allow extra args to be given to ggseqlogo::ggseqlogo, however universalmotif now implements its own motif plotting code directly with ggplot2.

#### view\_motifs

## Details

See compare\_motifs() for more info on comparison parameters.

See view\_logo() to plot from a numeric matrix with arbitrary values instead of a motif object.

Note: score.strat = "a.mean" is NOT recommended, as view\_motifs() will not discriminate between two alignments with equal mean scores, even if one alignment is longer than the other.

Note: if you want to plot the motifs yourself, you can set return.raw=TRUE to get the numeric motif matrices and calculate the polygon paths on your own or access the polygon path data directly from the final ggplot object using \$data.

## Value

A ggplot object. If return.raw = TRUE, a list of matrices.

#### Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

## See Also

```
compare_motifs(), add_multifreq(), view_logo()
```

#### Examples

```
## Plotting multifreq motifs:
data(examplemotif2)
view_motifs(examplemotif2, use.freq = 2)
```

```
## Generate your own letter set:
## Not run:
```

```
library(gglogo) # install from CRAN first if needed
fontDFtimes <- createPolygons(LETTERS, "Times", 800, scale = TRUE)
view_motifs(examplemotif2, fontDF = fontDFtimes)
```

```
## Note: setting `scale = TRUE` is necessary to properly align letters
## vertically, but this has the effect of horizontally stretching out
## letters which shouldn't be stretched (such as "I"). If you need to plot
## letters which have been badly horizontally scaled, you can fix them
## manually as demonstrated here:
```

```
# Retrieve the x-coordinates for the desired letter:
tofix <- fontDFtimes$x[fontDFtimes$group == "I"]
# Scale the letter x-coordinates:
tofix <- tofix * 0.35
# Remember to center the letter around 0.5 again:
tofix <- tofix + (1 - max(tofix)) / 2
# Apply the fix:
fontDFtimes$x[fontDFtimes$group == "I"] <- tofix
view_motifs(create_motif("AIG", alphabet = "AA"), fontDF = fontDFtimes)
```

write\_homer

## End(Not run)

write\_homer

Export motifs in HOMER format.

## Description

Convert DNA motifs to HOMER format and write to file. See <a href="http://homer.ucsd.edu/homer/motif/">http://homer.ucsd.edu/homer/motif/</a>.

#### Usage

```
write_homer(motifs, file, logodds_threshold = NULL, overwrite = FALSE,
append = FALSE, threshold = 0.8, threshold.type = c("logodds",
   "logodds.abs", "pvalue"))
```

# Arguments

motifs	See convert_motifs() for acceptable formats.		
file	character(1) File name.		
logodds_thresh	logodds_threshold		
	Deprecated. If set, read_homer() will behave like pre-version 1.12.0 of the universalmotif package for backwards compatibility (though a warning will be printed).		
overwrite	logical(1) Overwrite existing file.		
append	logical(1) Add to an existing file.		
threshold	numeric(1) Stringency required for HOMER to match a motif. See scan_sequences() for how to use this argument. Can be a single value to be recycled for all motifs, or a vector of equal length to the number of motifs.		
threshold.type	character(1) How the threshold value should be used to obtain the final threshold value in the written motif. See scan_sequences() for how to use this.		

## Value

NULL, invisibly.

## Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

## write\_jaspar

## See Also

read\_homer()

Other write\_motifs: write\_jaspar(), write\_matrix(), write\_meme(), write\_motifs(), write\_transfac()

## Examples

```
motif <- create_motif()
write_homer(motif, tempfile())</pre>
```

write\_jaspar Export motifs in JASPAR format.

## Description

Convert motifs to JASPAR format and write to file. See http://jaspar.genereg.net/.

# Usage

write\_jaspar(motifs, file, overwrite = FALSE, append = FALSE)

# Arguments

motifs	See convert_motifs() for acceptable formats.
file	character(1) File name.
overwrite	logical(1) Overwrite existing file.
append	logical(1) Add to an existing file.

# Value

NULL, invisibly.

## Author(s)

## See Also

```
read_jaspar()
```

Other write\_motifs: write\_homer(), write\_matrix(), write\_meme(), write\_motifs(), write\_transfac()

## Examples

write\_matrix Export motifs as raw matrices.

# Description

Write motifs as simple matrices with optional headers to file.

# Usage

```
write_matrix(motifs, file, positions = "columns", rownames = FALSE, type,
sep = "", headers = TRUE, overwrite = FALSE, append = FALSE,
digits = 6)
```

# Arguments

motifs	See convert_motifs() for acceptable formats.
file	character(1) File name.
positions	character(1) One of c('columns','rows').
rownames	logical(1) Include alphabet letters as rownames.
type	character(1) One of c('PCM', 'PPM', 'PWM', 'ICM'). If missing will use whatever type the motif is currently stored as.
sep	character(1) Indicates how to separate individual motifs. Set as NULL to have no separating lines between motifs (the default is to use a blank line).
headers	logical(1), character(1) Indicating if and how to write names.
overwrite	logical(1) Overwrite existing file.
append	logical(1) Add to an existing file.
digits	numeric(1) Number of digits to use for motif positions.

#### Value

NULL, invisibly.

# write\_meme

## Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

## See Also

## read\_matrix()

```
Other write_motifs: write_homer(), write_jaspar(), write_meme(), write_motifs(), write_transfac()
```

# Examples

```
motif <- create_motif()
write_matrix(motif, tempfile(), headers = ">")
```

write\_meme

# Export motifs in MEME format.

# Description

Convert motifs to minimal MEME format and write to file. See <a href="http://meme-suite.org/doc/meme-format.html">http://meme-suite.org/doc/meme-format.html</a>.

## Usage

```
write_meme(motifs, file, version = 5, bkg, strand, overwrite = FALSE,
    append = FALSE)
```

# Arguments

motifs	See convert_motifs() for acceptable formats.
file	character(1) File name.
version	numeric(1) MEME version.
bkg	numeric Background letter frequencies. If missing, will use background fre- quencies from motif objects (if they are identical); else background frequencies will be set to freq = 1/length(alphabet)
strand	character If missing, will use strand from motif objects (if identical); otherwise will default to "+ -"
overwrite	logical(1) Overwrite existing file.
append	logical(1) Add to an existing file. Motifs will be written in minimal format, so it is recommended to only use this if the existing file is also a minimal MEME format file.

## Value

NULL, invisibly.

#### References

Bailey TL, Boden M, Buske FA, Frith M, Grant CE, Clementi L, Ren J, Li WW, Noble WS (2009). "MEME SUITE: tools for motif discovery and searching." *Nucleic Acids Research*, **37**, W202-W208.

## See Also

#### read\_meme()

```
Other write_motifs: write_homer(), write_jaspar(), write_matrix(), write_motifs(), write_transfac()
```

## Examples

write\_motifs Export motifs in universalmotif format.

## Description

Write motifs as universalmotif objects to file. For optimal storage of universalmotif class motifs, consider using saveRDS() and readRDS(). Currently the universalmotif format is YAML-based, but this is subject to change.

## Usage

```
write_motifs(motifs, file, minimal = FALSE, multifreq = TRUE,
    progress = FALSE, overwrite = FALSE, append = FALSE, BP = FALSE)
```

#### Arguments

motifs	See convert_motifs() for acceptable formats.
file	character(1) File name.
minimal	logical(1) Only write essential motif information.
multifreq	logical(1) Write multifreq slot, if present.
progress	logical(1) Show progress.
overwrite	logical(1) Overwrite existing file.
append	logical(1) Add to an existing motif file. Package version in existing motif file must be greater than 1.2.0.
BP	<pre>logical(1) Allows for the use of BiocParallel within write_motifs(). See BiocParallel::register() to change the default backend.</pre>

## write\_transfac

#### Value

NULL, invisibly.

# Author(s)

Benjamin Jean-Marie Tremblay, <benjamin.tremblay@uwaterloo.ca>

## See Also

Other write\_motifs: write\_homer(), write\_jaspar(), write\_matrix(), write\_meme(), write\_transfac()

write\_transfac Export motifs in TRANSFAC format.

## Description

Convert motifs to TRANSFAC format and write to file.

# Usage

write\_transfac(motifs, file, overwrite = FALSE, append = FALSE)

## Arguments

motifs	See convert_motifs() for acceptable formats.
file	character(1) File name.
overwrite	logical(1) Overwrite existing file.
append	logical(1) Add to an existing file.

## Value

NULL, invisibly.
